This new WRIGHT'S preparation has been specially produced for pre-operative "scrub-ups" and satisfies the need for quick and certain destruction of infective agents.

Bacteriological tests prove that, under the usual conditions of washing the hands and arms, most pathogenic organisms are completely killed by Wright's Coal Tar Liquid Surgical Soap in less than half a minute. The rate of sterilization, using four common organisms of widely different types, is indicated in the accompanying table.

Hospitals are now using this new WRIGHTS liquid surgical soap in the operating theatres. It will prove invaluable in the surgery.

ANALYTICAL REPORT

ORGANISM	TYPE	TIME TO PRODUCE COMPLETE STERILITY AT 37°C	
		At a dilution of 1:100	At a dilution of 1:50
Streptococcus haemolytica	Gram positive	less than 1/2 min.	less than 1/2 min.
Staphylococcus Aureus	Gram positive	less than 1 min.	less than 1/2 min.
Salmonella Typhi	Gram negative	less than 1/2 min.	less than 1/2 min.
Proteus Vulgaris	Gram negative	more than 2 mins.	less than 1/2 min.

PRICE, tax inc. 14/- per 1/2 gallon. Free package and delivery from:

ROBINSON'S

Robsoup

**THE NEW WEANING FOOD
FOR BABIES**

ROBSOUP is a concentrated bone and vegetable soup, ready cooked in powder form. The food constituents are different from and complementary to those of milk mixtures and cereals.

Robsoup mixes instantly with water at all temperatures to any consistency from a thin broth, suitable for adding to the baby's bottle, to a thick soup which may be fed from cup and spoon.

Robsoup is simple to use and economical—a 1½ lb. tin gives ten helpings for a baby of five months. There is no waste with Robsoup. Only the amount required for the next meal is mixed at any one time. Being a dry powder, what is left in the tin will not go bad.

Therefore, provided the water used for mixing has been boiled and the cup and spoon are clean, Robsoup is safe from the danger of food infection and will not occasion gastro-enteritis.

Robsoup is made by a new process from peas, potatoes, carrots, yeast extract, cabbage, gelatin, edible bone phosphate, salt and onion. It is rich in iron (12 mg. per 100 gms.), calcium (400 mg. per 100 gms.) and vegetable protein (15.5%). Robsoup may therefore be given either as the first addition to milk or as the next step in weaning after the introduction of a cereal. Extensive tests have shown that babies thrive on Robsoup and like its flavour.

The facts about Glucose

Glucose, a term used to include a substance resulting from the partial hydrolysis of starch, is in practice a general description rather than a precise one. It is applied to medical preparations which contain additives that may not always be wanted and to commercial products of varying degrees of refinement. To identify Glucose in its purest form, and only in this form, the term Dextrose is used.

Dextrose, as found in the blood and tissues, is the sugar into which the body converts all carbohydrates. Requiring neither digestion nor chemical alteration, Dextrose is used by the body as a source of immediate energy.

The Dextrose (pure medicinal Glucose) produced by the Pharmaceutical Division of Corn Products Company Limited is prepared in two convenient forms:—

Dextrosol Powdered Glucose

This contains no additives of any kind. It can be taken in large quantities without causing nausea, and should be prescribed in all cases where a patient needs a source of heat and energy with the least demand on the digestion. Packed in 1 lb. cartons.

Dextrosol Karo Glucose Syrup

for Infants and Children

An appetising blend of pure Glucose and selected carbohydrates, carefully balanced to provide the ideal sugar-addition to the milk diet of artificially-fed infants. Of special value in cases of nutritional disorder. Spread on rusks, bread, etc., it offers an excellent supplementary source of energy for growing children. Packed in 1 lb. tins. A Karo Baby Book is available for the guidance of mothers.

Professional samples of both Dextrosol products will be gladly provided. For further information, doctors are invited to write to the Dextrosol Information Bureau, Wellington House, 125/130 Strand, London, W.C.2.

Prescribing a Laxative

When the Physician is called upon to prescribe a laxative for prolonged or occasional use, Andrews merits special consideration. Andrews is pleasant tasting. Its effervescence has a refreshing quality that makes it an acceptable draught. Andrews causes no griping or discomfort. Its laxative action is due to the presence of magnesium sulphate and other salts in balanced proportion, which, acting by osmosis, induce easy, painless evacuation.

Andrews is particularly suitable for patients liable to digestive upsets. It allays gastric discomfort and nausea. It also improves the flow of bile, and helps to check biliousness and sick headaches. No costive reaction results when Andrews is discontinued.

Active constituents:

Tartaric Acid ..	24.600%
Sodium Bicarbonate ..	25.142%
Magnesium Sulphate ..	19.000%
(B.P.C. Exsicc.)	
Sugar ..	31.250%
Saccharin ..	0.008%

FROM HEALTH FOOD STORES AND LEADING CHEMISTS

For oral
cleanliness

To keep the teeth and mouth clean without doing damage to either — that is the simple function of a good Tooth Paste. Macleans performs it. Macleans Peroxide Tooth Paste removes greasy film from the teeth. The polishing ingredients can then act easily and without abrasive action. They are ultimately soluble in saliva and leave no solid residues in the mouth.

... and
oral health

Macleans Peroxide Tooth Paste is sufficiently alkaline to mitigate oral acidity. It neutralises the acid patches formed on or between the teeth by fermenting food particles. It is mildly antiseptic but uninjurious to the normal oral flora which defend the mouth against pathogenic bacteria. It is pleasant to use and of refreshing flavour.

Sample tubes of Macleans Peroxide Tooth Paste are now available for distribution to your patients. A supply of these, and copies of a leaflet "The Care of the Mouth before and after the Extraction of Teeth," will gladly be sent to you free on request. This offer applies only to Great Britain and Northern Ireland.

The case of the exacting surgeon

A famous surgeon was struck by the fact that his razor blades seemed to be much sharper and more uniform than any scalpels he could then obtain. To a keen and vigorous mind there seemed no reason why the makers of the blades should not make surgical blades of the same high quality.

The solution was indeed brilliantly simple. He asked Gillette to produce surgical blades with edges equal to those of their razor blades. Now the sharpest edge in the world is available to make surgery easier, safer, and more accurate.

Gillette Surgical Blades and Handles are precision-made for each other. Not only does this ensure absolute rigidity in use, it makes the fixing and release of a blade the work of a moment.

Available throughout the world from leading distributors.

Gillette Industries Limited, Great West Road, Isleworth, Middlesex

R

For the effective
relief of

"Night Cough"

associated with acute and
Chronic Bronchitis

TERPOIN Elixir has long enjoyed high reputation with physicians throughout Great Britain and overseas for the effective relief it affords in all conditions of the respiratory tract characterised by excessive coughing. TERPOIN is presented in a palatable syrup base of bright golden colour and is well-tolerated and accepted by young and old. It is expectorant, mildly antiseptic, sedative and does not induce cerebral depression.

TERPOIN is thus indicated in the distressing and exhausting "night cough" so frequently associated with acute and chronic bronchitis, bronchial asthma and pulmonary tuberculosis. Alleviation is prompt and restful, recuperative sleep, so valuable in the treatment of such conditions, is ensured.

Clinical samples and literature
gladly, on request.

APPOINTMENTS

Applicants should state name, address, age, nationality, qualifications, and enclose 3 copies (unless otherwise specified) of recent testimonials with short statement of experience and appointments held.

Applications should be sent at once if no closing date is given.

Canvassing in any form will disqualify.

★SERVICE MEMBERS may have difficulty in supplying recent testimonials, but this should not deter them from applying.

Deferment of call-up for "R" practitioners (i.e., practitioners liable for call-up under the National Service Acts) is granted at the discretion of the Central Medical War Committee and (in Scotland) the Scottish Central Medical War Committee. The Committees normally allow an "R" practitioner to hold a First House Officer post (N.H.S. salary £350 per annum) provided that he obtains it without delay. Under present arrangements the Committees also normally allow an "R" practitioner to hold a Second House Officer post (£400) and a Senior House Officer post (£670), provided in each case that the higher appointment is secured before the termination of the practitioner's current appointment.

"R" practitioners may not accept Third House Officer posts (£450 per annum) unless they have obtained the special permission of the C.M.W.C. or (in Scotland) the Scottish C.M.W.C.

SALARY SCALES OF JUNIOR GRADES OF HOSPITAL MEDICAL STAFF

Regular Grades, Whole-time

(a) **REGISTRAR**: Posts obtained normally not less than two years after registration as a medical or dental practitioner and held normally for two years: £775 per annum in the first year; £890 per annum in the second and any subsequent years.

(b) **SENIOR REGISTRAR**: Posts obtained normally not less than four years after registration as a medical or dental practitioner and held normally for three years. £1,000 per annum in the first year; £1,100 per annum in the second year; £1,200 per annum in the third year; £1,300 per annum in any subsequent years.

Other Grades, Whole-time

(a) **HOUSE OFFICER**: £350 per annum for the first post held, £400 per annum for the second post held; £450 per annum for the third and any subsequent post held; with, in each case, a deduction at the rate of £100 per annum in respect of board and lodging and other services provided. Each post shall be tenable for six months.

The Minister will be prepared to authorize, in exceptional circumstances, salaries up to £50 per annum higher than the standard rates specified above where a post cannot be filled otherwise.

(b) **SENIOR HOUSE OFFICER**: Posts obtained normally not less than one year after registration as a medical or dental practitioner and normally held for one year only: £670 per annum.

(c) **JUNIOR HOSPITAL MEDICAL OFFICER**: Officers who have held house appointments but who are not registrars and who have less responsibility than other hospital officers of non-consultant status: £700 (for an officer appointed not less than two years after registration as a medical practitioner) by £50 to £1,000 per annum.

ALL NATIONAL HEALTH SERVICE HOSPITAL APPOINTMENTS ARE IN ACCORDANCE WITH THE TERMS AND CONDITIONS OF SERVICE OF HOSPITAL MEDICAL STAFF

Those intending to apply for resident appointments in the Registrar grades are recommended to make inquiries with regard to the deductions proposed for board and lodging at the time of submitting their applications, where this is not stated in the advertisement.

RESIDENT HOUSE OFFICER
 for a period of six months as from March 1, 1952. The successful applicant will also act as Clinical Assistant to Alder Hey Children's Hospital and this post is recognized for the D.C.H. examination. A salary of £50 per annum in excess of those set out in the terms and conditions of service of hospital medical and dental staff has been authorized. Applications, stating age, qualifications (with dates), experience and details of present and previous appointments, together with copies of three recent testimonials, should be sent to the undersigned immediately.—H. R. Mason, Secretary to the Committee, Alder Hey Children's Hospital, Liverpool, 12. (6809)

WREXHAM, POWYS AND MAWDACH HOSPITAL MANAGEMENT COMMITTEE

Applications are invited for the appointment of
PAEDIATRIC HOUSE PHYSICIAN
 for newly formed unit under Consultant Paediatrician for duty mainly at Maelor General Hospital, Wrexham (600 beds), and War Memorial Hospital, Wrexham (170 beds). The appointment will be for six months and will commence at beginning of March. Salary will be at the rate of £350 to £450 per annum, according to experience, less £7.00 per annum for full residential accommodation. Applications, stating age, nationality, qualifications and experience, with copies of two recent testimonials, to be addressed to the Secretary, Wrexham, Powys and Mawddach Hospital Management Committee, Maelor General Hospital, Croesnewydd Road, Wrexham. (6616)

MANSFIELD AND DISTRICT GENERAL HOSPITAL (211 beds)

Applications are invited for the post of
HOUSE SURGEON
 with duties in the Paediatric Department. Salary £350 to £450, according to previous posts held, with deduction of £100 in respect of residential emoluments. Applications, stating age, qualifications, and experience, together with names of two referees, to be forwarded to the Secretary, Mansfield Hospital Management Committee, Crow Hill Drive, Mansfield, Notts, as soon as possible.—A. Ashworth, Secretary to the Committee. (4813)

SOUTHAMPTON CHILDREN'S HOSPITAL
(Recognized by Conjoint Board for D.C.H.)

HOUSE OFFICER
 Post vacant February 17. Salary, etc., as nationally advocated. Preference given to candidates intending to specialize in paediatrics. Applications, with copies of testimonials, to be submitted as soon as possible to the Secretary, Southampton Group Hospital Management Committee, Bullar Street, Southampton. (5802)

PATHOLOGY**HITCHIN, LISTER HOSPITAL**

North-West Metropolitan Regional Hospital Board
 Applications are invited for the appointment of
WHOLE-TIME ASSISTANT PATHOLOGIST
 Salary scale £1,300 to £1,750 per annum. Possession of higher qualification desirable and candidates should have wide experience in pathology with special interest in morbid anatomy. This is a general hospital of some 400 beds with the usual special departments. Applications, stating date of birth, qualifications and experience, and the names of three referees, should reach the Secretary, North-West Metropolitan Regional Hospital Board, 11a, Portland Place, W.1, not later than February 23. Candidates are welcome to visit the hospital by direct appointment with Medical Director. (6810)

LEEDS REGIONAL HOSPITAL BOARD

Applications are invited from suitably qualified practitioners for the whole-time, non-resident post of
ASSISTANT PATHOLOGIST (S.H.M.O. Scale)
 for duties at hospitals in the Halifax Group. The successful candidate will work under the general guidance of the Consultant in charge of the department and will be required to reside in Halifax or within such distance of that town as the Board may approve. Applications, stating age, qualifications, and details of present and previous appointments (with dates), together with the names of three referees, should be forwarded to the Secretary, Park Parade, Harrogate, not later than February 16, 1952. (6605)

MANCHESTER REGIONAL HOSPITAL BOARD

Applications are invited for the whole-time non-resident post of

ASSISTANT PATHOLOGIST

to the Group Laboratory at Withington Hospital, with main duties at Christie Hospital and Holt Radium Institute, Manchester. Experience in all branches of hospital pathology is desirable, but special interest in morbid anatomy and histology (particularly of malignant disease) would be advantageous. The successful candidate will work under the general guidance of consultants. Salary £1,300 by £50 to £1,750. Forms of application can be obtained from the Senior Administrative Medical Officer, Manchester Regional Hospital Board, Cheetwood Road, Manchester, 8, and should be returned, with the names and addresses of three referees, to be received not later than February 7, 1952. (6867)

BIRMINGHAM REGIONAL HOSPITAL BOARD

Applications are invited for the following whole-time appointments:

REGISTRAR IN PATHOLOGY

Birmingham (Selly Oak) Group
 Duties mainly at Selly Oak Hospital, Birmingham (1,098 beds). Appointment may be resident or non-resident. Experience in specialty essential, and possession of higher qualifications an advantage.

REGISTRAR IN PATHOLOGY

Coventry Group
 Duties at Group Laboratory at Coventry and Warwickshire Hospital. Applicants must have some experience in Pathology, and an interest in Haematology is desirable.

Appointments subject to National Health Service (Superannuations) Regulations. Ten copies of applications, stating name, age, nationality, qualifications, present and previous appointments, and details of three referees, to Secretary, 10, Augustus Road, Birmingham, 15, before February 4, 1952. Candidates for both appointments should forward 15 copies of application. Candidates may visit the hospitals concerned. (6852)

LEEDS REGIONAL HOSPITAL BOARD

Applications are invited for the appointment of
NON-RESIDENT REGISTRAR in Pathology
 for duties at hospitals in the Halifax Group. This post offers good facilities for training in pathology, and is normally tenable for two years, subject to satisfactory service. Applications, stating age, qualifications and details of present and previous appointments (with dates), together with names of three referees, should be forwarded to the Secretary, Joint Registrars Committee, Park Parade, Harrogate, not later than February 2, 1952. (6677)

PRESTON ROYAL INFIRMARY (400 beds)
RESIDENT SENIOR HOUSE OFFICER (Pathological)

Applications should be made immediately to the Secretary, Preston and Chorley Hospital Management Committee, Royal Infirmary, Preston.—John Gibson, Secretary. (6762)

TAUNTON AND SOMERSET HOSPITAL
(Mussgrove Park Branch and East Reach Branch)
Taunton Hospital Management Committee

Applications are invited from registered medical practitioners for the following post:
SENIOR HOUSE OFFICER (Pathologist)
 Salary £670 per annum. Applications, stating age, qualifications (with dates), nationality and details of experience, together with two recent testimonials, should be sent immediately to the Secretary, Taunton Hospital Management Committee, Mussgrove Park Hospital, Taunton, Somerset. (6653)

WATFORD, GROUP NO. 9 LABORATORY
Peace Memorial Hospital

North-West Metropolitan Regional Hospital Board
 Applications are invited from registered medical practitioners for the post of

NON-RESIDENT JUNIOR PATHOLOGIST

(Senior House Officer grade)
 The appointment will be tenable for a period of one year in the first instance. Previous experience is desirable, but not essential. Salary and conditions of service will be as laid down in the National Health Service regulations. Applications, stating age, qualifications, and experience, together with the names of two referees, should be sent to the Pathologist in Charge at the above named Laboratory. (6720)

PSYCHIATRY**BRITISH HOSPITAL FOR FUNCTIONAL NERVOUS DISORDERS**
72, Camden Road, N.W.1

North-West Metropolitan Regional Hospital Board
 Applications are invited for the appointment of
TWO PSYCHIATRISTS (Consultant)
 each for two half days a week. Applicants should possess appropriate higher qualifications and have wide experience in this specialty. It will be an advantage for one of those appointments for applicants to have had experience in group therapy. Applications, stating date of birth, qualifications and experience, with the names of three referees, should reach the Secretary, North-West Metropolitan Regional Hospital Board, 11a, Portland Place, W.1, not later than February 23, 1952. Candidates are welcome to visit the hospital by direct appointment with the Secretary of the hospital. (6812)

SOUTH-WEST METROPOLITAN REGIONAL HOSPITAL BOARD

Applications are invited for the appointment of
DEPUTY PHYSICIAN SUPERINTENDENT AND CONSULTANT PSYCHIATRIST

at Tooting Bee Hospital, S.W.17 (2,300 beds)
 Patients are mainly senile and chronic psychotics, but acute cases of mental disorder are received. Candidates should possess the D.P.M. and preferably a higher medical qualification and should have wide experience in all modern methods of psychiatric treatment. The appointment is a resident one; a house being available in the hospital grounds at an appropriate rental. Applications (five copies), stating date of birth, qualifications, experience and present appointment(s), and giving the names and addresses of three referees, should be made by letter and sent to the Secretary (S.D.1), South-West Metropolitan Regional Hospital Board, 11a, Portland Place, London, W.1, to arrive not later than February 16, 1952. Applicants may visit the hospital by local arrangement. (6617)

BASINGSTOKE, HANTS, PARK PREWETT HOSPITAL (1,400 beds)

South-West Metropolitan Regional Hospital Board
 Applications are invited by the Board for the whole-time appointment of

DEPUTY PHYSICIAN SUPERINTENDENT and CONSULTANT PSYCHIATRIST

at the above hospital. The post is residential with a house available within the curtilage of the hospital, at a charge of £111.68 per annum. Candidates should possess the D.P.M. and preferably a higher medical qualification and have had extensive psychiatric experience, together with some practical knowledge in the administration of a mental hospital. Duties will include work at out-patient clinics (Aldershot, Odstock and Park Prewett Hospitals), psychotherapy at H.M. Prison, Winchester, and domiciliary work. Applications (five copies), stating date of birth, qualifications, experience and present appointment, and giving the names and addresses of three referees, should be made by letter and sent to the Secretary (S.D.1), South-West Metropolitan Regional Hospital Board, 11a, Portland Place, London, W.1, to arrive not later than February 16, 1952. Applicants may visit the hospital by local arrangement. (6678)

IMPORTANT: All intending applicants should read the revised NOTICE at the top of page 22

Psychiatry—contd.

PUBLIC HEALTH

(See Important Notice page 25)

BIRMINGHAM, CITY OF, EDUCATION COMMITTEE

Applications are invited for appointment of **ASSISTANT SCHOOL MEDICAL OFFICER** in the School Health Service.
Candidates must have had at least three years' experience in the practice of their profession subsequent to obtaining a registrable qualification. Salary £850 by annual increments of £50 to £1,150 per annum. Previous experience in local Government service may be taken into account. Travelling expenses allowed. Forms of application (to be returned not later than Monday, February 11), together with further information, obtainable from the undersigned on receipt of a stamped, addressed foolscap envelope. Communications should be endorsed "Assistant School Medical Officer." Canvassing will disqualify.—E. L. Russell, Chief Education Officer, Education Office, 74/5, Broad Street, Birmingham, 15. (6896)

CAERNARVONSHIRE COUNTY COUNCIL ASSISTANT COUNTY AND SCHOOL MEDICAL OFFICER

Applications are invited for the above post from those possessing the Diploma or Certificate in Public Health. The salary scale will be £850 by £50 to £1,150, and the commencing salary on this scale may be determined by the length of service in a similar post. Opportunities are available for gaining experience in public health administration. Travelling and subsistence allowances will be paid in accordance with national scales. A knowledge of Welsh is desirable. Further information may be obtained from the County Medical Officer of Health. Applications, giving complete particulars of training and experience, together with copies of two recent testimonials and the names of two referees, should be sent to the undersigned by not later than January 31, 1952.—Gwilym T. Jones, Clerk of the County Council, County Offices, Caernarvon. (5866)

CROYDON, COUNTY BOROUGH OF DEPUTY MEDICAL OFFICER OF HEALTH AND DEPUTY SCHOOL MEDICAL OFFICER

Applications are invited for this appointment from male registered practitioners with a Diploma of Public Health, and previous experience in a Public Health Department. The duties will be partly administrative, and partly clinical. Salary £1,470 per annum, rising by annual increments of £100, and a final one of £50 per annum, to a maximum of £1,720 per annum. Applications, on forms obtainable from the Medical Officer of Health, 45, Wellesley Road, Croydon, must be returned to him by February 2, 1952. No living accommodation is offered. Canvassing will disqualify.—E. Taberner, Town Clerk. (6887)

KENT COUNTY COUNCIL City of Rochester and the Borough of Chatham DEPUTY MEDICAL OFFICER OF HEALTH AND ASSISTANT COUNTY MEDICAL OFFICER

Applications are invited from practitioners holding the Diploma in Public Health or similar qualification for the above mixed appointment at a salary, with travelling expenses, in accordance with the recent Industrial Court award. The successful candidate will be required to devote 75 per cent of his time to duties for the County Council in the services concerning the care of mothers and young children and school health, for which an appropriate proportion of the salary £850 by £50 to £1,150 for an Assistant County Medical Officer will be paid. For the remaining 25 per cent of his time the officer appointed will act as Deputy Medical Officer of Health in Rochester and Chatham and these responsibilities will include duties in the Rochester Port Health Service. The amount payable for these duties being 25 per cent of the Deputy Medical Officer of Health's salary scale. The appointment will be required to pass a medical examination. Applications, stating age, qualifications and experience, together with the names of two persons to whom reference may be made as to professional experience and character, should be sent to the County Medical Officer, County Hall, Maidstone, not later than January 31, 1952. Any form of canvassing will disqualify.—W. L. Platts, Clerk of the County Council, County Hall, Maidstone. (6734)

CUMBERLAND COUNTY COUNCIL MILLOM RURAL DISTRICT COUNCIL
Applications are invited for the mixed appointment of

MEDICAL OFFICER OF HEALTH Milloom Rural District Council, and
ASSISTANT COUNTY MEDICAL OFFICER at a salary within the range of £1,192, rising by six increments to £1,500 under the Industrial Court award (2321), plus travelling, subsistence, etc., allowances. Applicants should be registered medical practitioners holding a Diploma in Sanitary Science, Public Health or State Medicine. Further particulars and forms of application may be obtained from the County Medical Officer, 11, Portland Square, Carlisle, to whom applications should be submitted before February 14, 1952.—G. N. C. Swift, Clerk of the County Council, W. N. Kitchin, Clerk to the Milloom Rural District Council. (6713)

GLAMORGAN EDUCATION AUTHORITY Rhondda Urban District Council Committee for Education

Applications are invited from registered medical practitioners for appointment as
MALE ASSISTANT MEDICAL OFFICER under the supervision of the District School Medical Officer at a salary of £850 per annum, rising by annual increments of £50 to £1,150 per annum. Preference will be given to candidates holding the D.P.H. or D.C.H., and experience in paediatrics will be an advantage. The successful candidate, if in need of housing accommodation and not already a resident of the Rhondda Urban Area, may be offered the tenancy of a Council house. Forms of application and conditions of appointment may be obtained from the District School Medical Officer, Tydfil House, Pentre, Rhondda, by whom completed applications should be received as soon as possible.—D. J. Jones, Clerk of the Council. (5867)

GLASGOW, CORPORATION OF THE CITY OF
Applications are invited from qualified medical women for posts as**ASSISTANT MEDICAL OFFICERS in the Maternity and Child Welfare Service of the Health and Welfare Department**

The work carried out by the officers will be principally in connexion with ante-natal and post-natal supervision, but they may be required by the department to carry out other maternity and child welfare duties. This supervision of the expectant mother is being developed in co-operation with the Western Regional Hospital Board. Applicants must have postgraduate experience in obstetrics and the possession of the D.R.C.O.G. will be an advantage. The salary scale for the appointments is £850, rising by annual increments of £50 to £1,150 per annum, with placing according to qualifications and experience. The posts are superannuable and successful applicants will be required to undergo medical examination. Applications, stating age, qualifications, and full details of training and experience, together with copies of not more than three recent testimonials, or the names of three referees, to be lodged with the undersigned in an envelope marked "Appointments—Assistant Medical Officers (Maternity and Child Welfare)" not later than January 26, 1952.—William Kerr, Town Clerk, City Chambers, Glasgow. (6733)

BRITISH EMPIRE CANCER CAMPAIGN invites applications from British subjects for Exchange Fellowships in Cancer Research offered by the National Cancer Institute of Canada and the American Cancer Society. Completed applications must be received by February 29, 1952. Fellowships are of one year's tenure at a stipend of \$4,000. Travelling expenses to and from centre of work will be borne by the Campaign. For further particulars and application forms apply to the Secretary-General, British Empire Cancer Campaign, 11, Grosvenor Crescent, Hyde Park Corner, London, S.W.1. (5405)

GREY HOSPITAL, Greymouth, New Zealand PATHOLOGIST

Applications from registered medical practitioners with training and experience in pathology are invited for the above position. Commencing salary at rate of £1,260 to £1,660 (N.Z.) per annum, according to qualifications and experience. A new laboratory is in course of erection. The position is non-resident and housing will be appointee's own responsibility. Annual leave and sick leave are prescribed in regulations. Reasonable travelling expenses incurred by an overseas appointee will be refunded up to £150 for single man and £400 for married man accompanied by dependent relatives. The appointment is terminable by three months' notice on either side. Applicants are advised to obtain further particulars from the office of the High Commissioner for New Zealand, 415, Strand, London, W.C.2. Applications (by air mail) close with the undersigned on March 31, 1952.—W. H. J. Watson, Managing Secretary, Grey Hospital Board, Greymouth, New Zealand. (6757)

OTAGO HOSPITAL BOARD

Dunedin Hospital and University of Otago
Applications are invited for the position of
HALF-TIME OPHTHALMIC SURGEON
to the Department of Ophthalmology at Dunedin Hospital

Salary, commencing at a rate between £800 to £1,000 per annum, according to qualifications and subsequently according to the Hospital Employment Salary Regulations shortly to be issued. Salary will commence on assuming duty at Dunedin Hospital. Full details may be obtained on application to the office of the High Commissioner for New Zealand, 415, The Strand, London, or to the office of this Journal. Applications, stating age, qualifications, postgraduate experience, accompanied by copies of testimonials, a certificate of health and radiological certificate and testimonials, will be received by the undersigned until 10 a.m. on February 20.—W. A. Williamson, Secretary, Otago Hospital Board, P.O. Box 453, Dunedin. (6902)

COLONIAL DEVELOPMENT CORPORATION MEDICAL OFFICERS

Required for service overseas. Experience of medicine and hygiene in tropical and sub-tropical climates particularly for native labour forces. Preferably having diploma tropical medicine and hygiene. Commencing £1,200 to £1,750 with house and hard furnishings at five per cent of emoluments. Outfit grant, general U.K. leave. Superannuation scheme. Normal tour 18 to 36 months. Write, giving full details, age, qualifications and experience, to Personnel Manager, 33, Dover Street, W.1, quoting Serial No. 84, by January 29. (6899)

UNIVERSITY OF SYDNEY, Australia

The Senate will shortly proceed to the appointment to the

CHAIR OF PATHOLOGY

which becomes vacant on the retirement of Professor W. K. Inglis. The salary will be at the rate of £2,500 (Australian) per annum, plus cost-of-living adjustment. There is a normal retirement provision under the Professorial Superannuation Scheme, and, in addition, a pension of £400 (Australian) per annum upon retirement after the age of sixty years. The Senate reserves the right to fill the Chair by invitation. Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 5, Gordon Square, London, W.C.1. The closing date for receipt of applications is March 31. (6777)

UNIVERSITY OF SYDNEY, Australia

The Senate will shortly proceed to the appointment to the

BOSCH CHAIR OF BACTERIOLOGY

which becomes vacant on the retirement of Professor H. K. Ward. Salary will be at the rate of £2,500 (Australian) per annum, plus cost-of-living adjustment. There is a normal retirement provision under the Professorial Superannuation Scheme, and, in addition, a pension of £400 (Australian) per annum upon retirement after the age of sixty years. The Senate reserves the right to fill the Chair by invitation. Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 5, Gordon Square, London, W.C.1. The closing date for receipt of applications is March 31. (6778)

HIS MAJESTY'S COLONIAL RESEARCH

SERVICE—East African Medical Survey
Vacancy exists in the above unit in Tanganyika for a

MEDICAL RESEARCH OFFICER

whose duties will include carrying out of physical examinations of Africans as part of a large scale medical survey of isolated populations. African assistants will be available. Candidates, who should be male and not over 35 years old, should hold medical qualifications registrable in the United Kingdom. Tropical experience is an advantage but not essential, as opportunities will be provided on arrival in East Africa of acquiring knowledge of local disease conditions, etc., if this is necessary. Emoluments (including Overseas research allowance) on scale £840 to £1,500 per annum, point of entry according to age and qualifications. Cost-of-living allowance also payable. Selected candidates may be required to proceed to East Africa by air. Official quarters are available for which rent is chargeable at the rate of 10 per cent of basic salary. Free passages for officer and his wife and children under 13 years. Outfit allowance of £60. Superannuation provided under Colonial Superannuation Scheme. Forms of application may be obtained from the Under Secretary of State, Colonial Office, Research Department, S 610, Sanctuary Buildings, Great Smith Street, S.W.1. (6776)

MUFULIRA COPPER MINES LIMITED**Northern Rhodesia**

Applications are invited for the post of
SENIOR MEDICAL OFFICER
Applicants should have had considerable experience in general surgery. Starting salary from £1,620, depending on qualifications and experience, plus cost-of-living allowance (at present £90 per annum) and bonus (at present 60 per cent on basic salary). Also pension and life assurance scheme. Write, Rhodesian Employment Department, Selection Trust Building, Mason's Avenue, Coleman Street, London, E.C.2. (6830)

HIS MAJESTY'S COLONIAL SERVICE, Malaya

Doctors having medical qualifications registrable by the General Medical Council in the United Kingdom, with one or more years' experience after qualification, are required for appointment as

MEDICAL OFFICERS AND MEDICAL OFFICERS OF HEALTH

for general medical and health duties. A limited number of practitioners liable for call up under the National Service Act, 1948, may apply, and if appointed will be granted indefinite deferment of call up on completion of a minimum period of one tour of three years in the Malayan medical service. Appointment is available (a) on probation for permanent establishment, (b) on employment from the National Health Service, and (c) on short term contract with gratuity. (a) **Permanent terms.** Subject to three years' probation, appointment is permanent with pension (non-contributory) at age 55. Salary is paid in the scale £952 by £42 to £1,204 to £1,274 by £42 to £1,652 per annum. There are many posts, specialist and administrative, available on promotion carrying higher salaries (up to about £2,400 for the highest post). Promotion is often made before reaching the top (£1,652) of the long scale. There is also a cost-of-living allowance at varying rates, according to family circumstances, subject to maximum of £336 per annum for single men and of £707 per annum for married men with children (both rates higher when stationed in Singapore). Note. Doctors with more than one year's approved experience after age 25 (including service in His Majesty's Forces) enter the salary scale at points above the minimum according to their experience; and four increments of salary are also given to holders of approved higher qualifications (e.g. F.R.C.S., M.R.C.P., D.P.M., D.A., etc.). (b) **National Health Service.** Doctors may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Malayan salary on leaving Malaya at the end of their engagements. Emoluments as under (a) including incremental credit for experience and higher qualifications as in note under (a). Doctors so appointed may be considered for permanent terms at any time during their Colonial employment provided they surrender their rights to the resettlement grant and payment by Malayan Governments of superannuation contributions. (c) **Contract terms.** The contract will be for three years' resident service, renewable for a further tour of three years by mutual agreement. Salary and cost-of-living allowance as under (a) including incremental credit for experience and higher qualifications as in note under (a). In addition a gratuity earned at the rate of £300 to £450 per annum, according to salary, is paid on expiry of contract. Doctors on contract may be considered for appointment to the permanent establishment at any time on their agreeing to surrender their gratuity earning rights. In all three types of appointment the rates of salary and gratuity refer to doctors eligible for expatriate terms under Malayan Regulations (i.e. those whose permanent homes are in the United Kingdom, Ireland, Australia, Canada, etc.). The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Income tax is payable at Malayan rates which are lower than those in the United Kingdom. Government quarters with heavy furniture are provided at a low rental, or an allowance is paid in lieu of quarters. Free passages are provided for the doctor, his wife, and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. The social and recreational facilities in Malaya are good. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No 27215/242/51). (5187)

UNIVERSITY APPOINTMENTS**WORLD HEALTH ORGANIZATION FELLOWSHIPS**

A small number of Fellowships is to be awarded in 1952 by the World Health Organization to registered medical practitioners, dental practitioners and State registered nurses of at least five years' standing who are engaged in the health services, medical education or medical research in the United Kingdom. Fellowships will be of two kinds: (1) Resident Fellowships for a period which exceptionally might be extended to one year. (2) Travelling Fellowships of short duration for senior persons holding responsible appointments. Applications, giving full particulars of qualifications, experience, proposed programme and duration of study, and accompanied by the names of two referees, should be sent (a) by those resident in Scotland to the Secretary, Department of Health for Scotland, St. Andrew's House, Edinburgh, 1; (b) by others to the Secretary, Ministry of Health, Savile Row, London, W.1. Envelopes should be marked "World Health Organization Fellowships" and received not later than February 2, 1952. (6904)

University Appointments—contd.

THE BRITISH EMPIRE CANCER CAMPAIGN invites applications for Fellowships in Cancer Research. These Fellowships will be intermediate between the Campaign's existing Senior and Junior Fellowships, and will normally be tenable for five years at a salary of £1,500 by £100 to £1,900 per annum. Fellowships are full-time and will carry superannuation. Fellowships are open to any person of British nationality who, at the date of election, has taken a degree in any faculty in any university in the British Empire approved by the campaign, or who, if a female, has passed an examination which would have entitled her, if a male, to take any such degree. The possession by a Fellow at the date of election of a medical diploma registrable in the United Kingdom will be accepted as a qualification for a Fellowship in lieu of a degree. Elections will take place in June, 1952, and work, if possible, should be begun before the end of the year. Fellows must carry on their research initially in Great Britain or in Northern Ireland, and only at the place at which they are authorized by the Campaign to work. The fares of successful candidates from overseas will be paid by the Campaign. The closing date for the receipt of applications is May 1, 1952. For further particulars and application forms apply to the Secretary-General, British Empire Cancer Campaign, 11, Grosvenor Crescent, Hyde Park Corner, London, S.W.1. (5404)

CRICHTON ROYAL FELLOWSHIPS

The Board of Management of the Crichton Royal have established three Fellowships for the training of specialists in psychiatry, each carrying a salary of £670, less a deduction of £150 for the usual residential emoluments. Two of these Fellowships will fall vacant on April 1, 1952. The Fellows receive training in all branches of clinical psychiatry, including work in out-patient and child guidance clinics, by the senior members of the medical staff. The Fellowships are tenable for one year but may be prolonged for another year. Previous general hospital experience essential. Application form and syllabus are obtainable from the Physician Superintendent, Crichton Royal, Dumfries. (6779)

WELSH NATIONAL SCHOOL OF MEDICINE (University of Wales)

Applications are invited for the post of **SENIOR LECTURER IN THE MEDICAL UNIT**. The person appointed will be required to assist in all the work of the Professorial Department of Medicine as directed by the Professor, and to take charge of hospital medical patients in his absence. The unit has 40 beds and good laboratory accommodation. The post is full-time and the salary will be within the scale £1,500 by £100 to £2,000 per annum. Schemes of superannuation and family allowances apply to the appointment. Further particulars may be obtained from the undersigned, by whom applications should be received not later than Thursday, February 14, 1952.—F. Dodsworth, Secretary, 34, Newport Road, Cardiff. (5764)

UNIVERSITY OF BRISTOL

Applications are invited for the post of **DEMONSTRATOR IN ANATOMY**. Salary £600 per annum. About half the Demonstrator's time will be spent on research for which facilities are available. Applications, giving full names, age, qualifications, details of education and experience, together with the names of not more than two referees, and copies of not more than three recent testimonials, should reach the undersigned, from whom further particulars may be obtained, on or before February 15, 1952.—H. C. Butterfield, Registrar and Secretary. (6832)

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL (Obstetric Unit)

Applications are invited for the post of **ASSISTANT in the Obstetric Unit**. Salary according to qualifications, but not less than £960 per annum, with superannuation and family allowance. The appointment will commence from March 1, 1952. Applicants must possess a University degree. The holder of the post will be required to sign an honorary contract to undertake duties in University College Hospital. Applications, with names of two referees, should be sent to the Secretary of University College Hospital Medical School, University Street, London, W.C.1, not later than fourteen days from the date of the appearance of this advertisement. (6833)

UNIVERSITY OF OXFORD

RADCLIFFE TRAVELLING FELLOWSHIP 1952
An examination for a Fellowship of the annual value of £300, tenable for two years, will be held at the University Museum on February 23, 1952. Candidates must have passed all the examinations for the Degree of Bachelor of Arts and Bachelor of Medicine, and must not have exceeded four years (exclusive of military service) from the time of passing the last examination for the Degree of Bachelor of Medicine. The examination will take the form of a self-chosen essay and an interview. Further particulars to be obtained from the Regius Professor of Medicine, University Museum, Oxford. All applications, with essays, must be sent in by January 31, 1952. (4342)

UNIVERSITY OF LEEDS

The Council invites applications from suitably qualified persons, either with or without a registrable medical qualification, for the **BROTHERTON CHAIR OF BACTERIOLOGY** which will become vacant on September 30 next on the retirement of Professor J. W. McLeod. Applications (fifteen copies), together with the names of three referees, should reach the Registrar, The University, Leeds, 2 (from whom further particulars, including salary range, may be obtained), not later than March 17, 1952. Applicants abroad may apply by cablegram naming three referees in the United Kingdom. (6780)

Lady seeks Receptionist post for doctor or dentist. Some experience. Can drive.—Box 257, B.M.J.
Lady desires post as Receptionist, Typing. Car driver. Used to responsibility. Personal references.—Box 202, B.M.J.

Stenographer, competent, seeks part-time post afternoons. Harley Street area preferred.—Lofts, 34, Devonshire Place Mews, W.1.
Trained Orthopaedic Nurse with one year's general nursing, seeks post as doctor's receptionist, willing to learn shorthand, typing.—Box 259, B.M.J.

Applicants requiring testimonials, theses, copied or duplicated, should communicate with Manton Secretarial Service, Ltd., 98, Victoria Street, S.W.1 (Victoria 0141), who are specialists.

Secretaries with good knowledge of shorthand, typing and medical terms supplied. Also hospital clerical staff.—M. & S. Employment Agency, 32, Queen Victoria Street, E.C.4. City 7131 (3 lines).
Thoroughly trained Medical Secretarial staff may be engaged through Brook Street Bureau, Ltd., 59, Brook Street, W.1. Gro. 6666, and 2, George Street, Croydon. Phone: 3363.

ACCOMMODATION

AVAILABLE

Norfolk Hall, 25, Norfolk Square, W.2. Quiet, well-appointed accommodation. Car parking facilities, from 4 guineas. Dinner, bed and breakfast. Resident Proprietor. Tel.: Pad. 8596.

WANTED

Wanted, Furnished Flat, two bedrooms, self-contained. 25 minutes Trafalgar Square. Middle March.—Box 235, B.M.J.

CONSULTING ROOMS, ETC.

AVAILABLE

Consulting Suite, ground floor, Portland Place. Full services. Reasonable rent. Lease. Fittings at cost. Share or let sessionally.—Box 248, B.M.J.

HOTELS

CORNWALL.—THE HARROCK MANOR and Farm. Jersey herd. Log fires. Come and enjoy our early spring now. Golf, St. Enodoc. Port Isaac 234.

MOTOR CARS, HIRE, ETC.

Brooklands of Bond Street for individuality in new and used cars. Sole London Distributors, Alvis, Aston Martin, Healey, Lagonda. Latest models. Ferrari concessionaires. Don't swerve from your purpose. Buy or sell your car at 103, New Bond Street, London, W.1. Mayfair 8351/6.

UP TO DATE?

IN these days when a doctor can hardly call his day his own but has still to find time to keep himself abreast of the latest developments in Medicine and Surgery, anything that can provide him with information on the latest advances in all fields of Medicine is welcome.

THE two monthly Journals, *Abstracts of World Medicine* and *Abstracts of World Surgery*, are designed to do this. They provide the profession with easily assimilated information on current world intelligence on every aspect of medical practice and science.

In Para-nasal infections **ARGYROL** provides
physiological action
without CNS stimulation
or rebound congestion

● A return to normal function by the decongestive, demulcent and bacteriostatic actions of ARGYROL is achieved without the side effects and rebound so frequent with many vasoconstrictors. In the solution of para-nasal problems, the ultimate advantages of using ARGYROL are readily apparent.

The ARGYROL Technique

1. The nasal meatus . . . by 20 per cent ARGYROL instillations through the nasolacrimal duct.
2. The nasal passages . . . with 10 per cent ARGYROL solution in drops.
3. The nasal cavities . . . with 10 per cent ARGYROL by nasal tamponage.

Its Three-fold Effect

1. Decongests without irritation to the membrane and without ciliary injury.
2. Definitely bacteriostatic, yet non-toxic to tissue.
3. Stimulates secretion and cleanses, thereby enhancing Nature's own first line of defense.

Decongestion and Relief without Rebound ●

Decongestion without Dysfunction

— the medication of choice in treating para-nasal infection

INTRODUCING
FOR THE FIRST TIME
IN THIS COUNTRY

FERROUS GLUCONATE

THIS MAJOR ADVANCE IN THE FIELD OF ORAL-IRON THERAPY

... is presented in ELIXIR CEREVON in combination with the important Vitamin B factors, aneurine hydrochloride, nicotinamide and riboflavin. Ferrous Gluconate possesses advantages over ferrous sulphate in that it is more readily absorbed by the stomach and utilized by the haemopoietic system without giving rise to gastric disturbance, even in patients who have shown intolerance to other forms of iron.

The high palatability of ELIXIR CEREVON is provided by 15% natural blackcurrant juice with glucose,

which assists absorption and provides each teaspoonful of the Elixir with 4.5 mgm. Vitamin C. INDICATIONS: For the treatment of the secondary anaemias of pregnancy and malnutrition and as a reconstructive tonic after severe illness.

FORMULA:

Ferrous Gluconate, 0.3 gm.

Aneurin. Hydrochlor., 1 mgm.

Riboflav., 1 mgm.

Nicotinamide, 10 mgm.

With trace elements of Copper and Manganese.

make a contribution to

The Treatment of Asthenia

Bulk manufacturing process

Full and rapid recovery from illness or following surgical operations may be the more readily achieved if liver extract, iron and vitamins are supplied to the patient to facilitate blood regeneration. Even a relatively small fall in the hæmoglobin level in patients otherwise reasonably healthy may manifest itself in the form of general asthenia and proneness to fatigue. HEPRONA, a preparation containing Hepatex liver

extract, iron, members of the Vitamin B complex and glycerophosphates, is an excellent tonic in such cases and is suitable both for adults and children.

WATCHFULNESS and PRENATAL CARE . . .

Prenatal

CAPSULES

Lederle

Especially during pregnancy, medical watchfulness and prenatal care—with careful attention to adequate nutrition—have been shown to pay rich dividends of health to both mother and child. The dietary factors for which demand is particularly intensified are proteins, minerals and vitamins. The need for them may be increased by as much as one hundred per cent.

The amount of protein in the diet can be calculated. However, clinical experience suggests that, since no practical method exists for assaying the mineral and vitamin content of the obstetric patient's diet, such supplementation is an important part of the management of pregnancy. The so-called toxæmias of pregnancy, it has been suggested, are in reality states of nutritional deficiency. Throughout the period of gestation, PRENATAL CAPSULES *Lederle* provide a balanced formula of vitamins and minerals—an important dietary supplement—to assure optimum reserves. Each constituent of PRENATAL CAPSULES assures a measurable daily supply of these essential nutritional factors for the pregnant woman to maintain, or to restore, a normal vitamin-mineral tissue balance.

Each capsule contains: Vitamin A, 2,000 I.U., Vitamin D, 400 I.U., Thiamine Hydrochloride (B_1), 2 mg., Riboflavin (B_2), 2 mg., Ascorbic Acid (C), 35 mg., Nicotinamide, 7 mg., FOLVITE* Folic Acid, 1 mg., Calcium (in $CaHPO_4$) 250 mg., Phosphorus (in $CaHPO_4$), 190 mg., Dicalcium Phosphate Anhydrous ($CaHPO_4$) 869 mg., Iron (in $FeSO_4$) 6 mg., Ferrous Sulphate Exsiccated, 20 mg., Manganese (in $MnSO_4$), 0.12 mg. *Regd. INAUGURAL LANGDON-BROWN LECTURE*

BY

The Late GEOFFREY EVANS, M.D., F.R.C.P.

We are assembled this afternoon to honour the memory of Sir Walter Langdon-Brown, and I will do my best to place on record something at least of the contribution he made to medical science and human understanding. I am very grateful to the President and Board of Censors for the honour of being appointed to give this Inaugural Lecture.

Bedford Days

Walter Langdon-Brown was born on August 13, 1870, in the old manse, Bedford, the eldest son of the Reverend Dr. John Brown, who was the sixth direct successor of John Bunyan in the pastorate of Bunyan Meeting, Bedford, and the author of the standard biography of Bunyan. He entered Bedford School in 1879 and there he showed himself very earnest in his work and keenly curious to know. Although a poor classical scholar judged by the school standard of those days, he won the prize for English essay each year, an achievement which confounded his masters, who held that the ability to write good English depended on a knowledge of the classics. By the age of 15 he had developed an enthusiasm for English literature, and two years later he was promoted top of the form. At the age of 18 he won a leaving scholarship and so ended his school days with credit.

His home life was a happy one. His father concerned himself with his schooling and took his son to Bedford School when he went there for the first time for his entrance examination. The boy admired his father; he realized that the headmaster of his school, Dr. J. S. Phillpotts, and his father were the intellectual leaders of the town. His mother was the deciding influence in his career in these early days. She seems to have been somewhat reserved, very firm in character, and puritanic in outlook—using the term "puritanic" in the sense of being extremely strict in morals. Mrs. Brown had complete faith in her eldest son; she watched his every step and did her best to guide him in the path of goodness. But he wanted more than this, an expressed affection, and he found in his sister Florence, later Mrs. J. N. Keynes, who was nine years older than himself and whom he adored, and to whom, to use his own words, he remained devoted throughout his life. With his brothers, Harold and Kenneth, he was lifelong friends. He was strong and constant in affection.

*Read, owing to the death of Dr. Evans on August 30, by the President of the Royal College of Physicians of London at the College on October 30, 1951.

Cambridge Days

Langdon-Brown entered St. John's College, Cambridge, with a junior scholarship in 1889. He arrived unsure of himself and diffident, but he soon made friends and became engrossed in his work. In his third year he found himself. He was by nature ambitious; his teachers gave him the encouragement and appreciation which were his greatest need at that time, and now he became conscious of a firmer grip on things and felt he was beginning to approach the first-class academic standard.

He has left us a beautiful vignette of an occasion in his life at St. John's College. "We take our places in hall along the long Jacobean benches at the equally long and ancient tables. The bell rings in the turret. The butler hands the Latin grace to the scholar of the week as he advances to the dais. We rise; the bell ceases; silence. 'Benedic, Domine, nos et dona tua,' he begins; 'Bless us, O Lord, and these thy gifts.' So has the grace run these four hundred years since the Lady Margaret, whose portrait hangs in the place of honour, founded the College. So it ran in the days when the great men whose portraits adorn the walls were undergraduates, became distinguished, died, and faded into memories more or less distinct. So it will run when we in our turn give place to others. What a deep sense of continuity it gives; of life that transcends the individual."

Langdon-Brown completed his career at Cambridge with distinction by gaining a first-class in both parts of the Natural Sciences Tripos. Subsequently he maintained the high standard which he had set himself by being bracketed first in surgery and midwifery and in being second in medicine in the third M.B. examination: later he was awarded the Horton-Smith Prize for the best thesis for the degree of M.D., University of Cambridge.

St. Bartholomew's Hospital

When Langdon-Brown delivered the Annual Harveian Oration in this College on October 19, 1936, he chose for his subject "The Background to Harvey." And so it is in keeping with his own approach to biography to speak about his background at St. Bartholomew's Hospital, more particularly in respect of its atmosphere of learning, to which he himself so greatly contributed.

Robert Bridges, later Poet Laureate, had left the hospital in 1881, 13 years before Langdon-Brown came

to St. Bartholomew's. It is appropriate, however, to mention his name, because Langdon-Brown was enthralled by his great work, *The Testament of Beauty*, and he chose "Robert Bridges: The Poet of Evolution," as the theme for his inaugural address to the Abernethian Society on November 3, 1931.

Langdon-Brown entered St. Bartholomew's Hospital in 1894 with the senior open entrance scholarship. In the same year Sir James Paget gave the inaugural address at the 100th session of the Abernethian Society. After qualification in 1896 he was appointed house-physician to Dr. Samuel Gee, a man of remarkable talent, whose mind was cast in the same mould as that of the seventeenth-century philosopher Thomas Hobbes, whose works he often quoted. This was the age of materialism at Bart's; reason disputed empiricism, and logic prepared the ground for the incursion of science into medicine. Norman Moore was assistant physician, later full physician, and, finally, President of this College during the years of Langdon-Brown's life at St. Bartholomew's Hospital. In addition to his knowledge of biology and natural history, Norman Moore was a scholar of Irish Gaelic. In those days, the notes of a patient's case were pinned on a board which was hung on the wall at the head of the bed for everyone to see, and Norman Moore would sometimes write a very private note on the patient in the ancient language of Erse, or a less private record was made in Latin, such as the diagnosis "valetudo conquassata" (literally translated, "health severely shattered"); meaning much the same as anxiety neurosis or battle fatigue. But his name in the future will be remembered by his *History of the Study of Medicine* in the British Isles, and by his editing of the Middle English translation of *Liber Fundacionis*, a work composed by an Augustinian canon in the Priory of St. Bartholomew in West Smithfield in the reign of King Henry II; and, especially will he be remembered by his great history of St. Bartholomew's Hospital.

This literary tradition was carried on by Langdon-Brown's contemporaries. Sir D'Arcy Power shared Sir Norman Moore's interest in historical research in his *Life of William Harvey*, published in 1897, while another of his colleagues, Sir Percival Horton-Smith Hartley, in conjunction with Harold Aldridge, has written the *Life of Johannes de Mirfeld*, who was one of the Clerks of the Priory of St. Bartholomew in Smithfield in the latter half of the fourteenth century, when Richard II was king. The latest contribution to historical research emanating from the hospital is a collection of *Essays in the History of Medicine* by the late George Gask, and no doubt Langdon-Brown heard some of these lectures delivered.

Sir Archibald Garrod introduced biochemistry to clinical medicine. He walked to and fro between his wards and Dr. Hurlley's chemical laboratory: to Garrod the wards and laboratory were as much one as the two sides of a penny. He was elected a Fellow of the Royal Society in recognition of his work on urinary pigment and his discovery and description of *Inborn Errors of Metabolism*, which was first published in book form in 1909; the second edition was published in 1923, when he was regius professor of medicine in the University of Oxford. Administrative capacity was represented by Sir Wilmot Herringham and by Sir Holburt Waring, who is still with us, both of whom in their time were vice-chancellors of the University of London. Herringham was a great orator; Waring was in the forefront of surgical practice.

Langdon-Brown had a wide education in clinical medicine. He served as clinical assistant in the department of diseases of the ear, nose, and throat, and then as external midwifery assistant. When he had completed his term as house-physician to Dr. Gee he became senior resident medical officer to the Metropolitan Hospital; two years later, in 1900, he was appointed assistant physician and pathologist to that hospital, and in 1906 became full physician. Meanwhile his progress at St. Bartholomew's Hospital was slow, but it provided him with ample opportunity for learning and clinical experience, first as casualty physician in 1900, then as junior demonstrator of practical medicine three years later, and, again three years later, he was appointed medical registrar and demonstrator of morbid anatomy. It was not until 1913, at the age of 43, that he was elected assistant physician to St. Bartholomew's Hospital. It was a long and arduous climb to the Staff at Bart's in those days. He became full physician in 1924 at the age of 54. Meanwhile he had already made his name and fame by his work on war nephritis, undertaken at the request of the Medical Research Council and the Director-General of the Army Medical Service in 1915, and his Croonian Lectures, delivered in this College in 1918. That his name was known outside this island of ours is shown by his having been invited to lecture at the American Academy of Medicine in New York in 1929. It was very hard on him that on account of the appointment of a full-time professor of medicine at Bart's in 1920 he was not elected full physician in that year. But all this time he was teaching and working with great energy and perseverance. His book *Physiological Principles in Treatment* appeared in successive editions, and in 1927 he published his book on endocrinology for the use of general practitioners, *The Endocrines in General Medicine*, in which he gave an account of the endocrine system in relation to the autonomic nervous system.

Physiology

Langdon-Brown brought an entirely new outlook on clinical medicine to this seat of learning. He was a physiologist at heart and kept himself informed on advances in this subject throughout his active professional life.

During his early years of clinical practice he taught physiology, first as junior demonstrator in 1899 and then as demonstrator of physiology in 1902, an appointment which he held for a number of years. And so his first contribution to clinical medicine was the interpretation of the signs and symptoms of disease in terms of physiological reactions; at the same time he began to put therapeutics, or the treatment of disease, on a scientific as opposed to an empirical basis. In October, 1908, the first edition of his *Physiological Principles in Treatment* was published. The book was written to acquaint the busy practitioner with the leading changes in physiology, so that he might deduce from it, the points on which his clinical conceptions should be modified. He was helped by Dr. Reginald Hilton in the preparation of the eighth edition, published in December, 1942, when the book had already been 34 years in circulation, in itself a notable indication of its value.

His interest in physiology was aroused by his teachers, and by Gaskell in particular. His interest in endocrinology, the ductless glands, had its origin in his own work and observation. One Easter he stayed

up at Cambridge, by special permission, to study embryology. He incubated hens' eggs, stopping their growth at different stages and cutting serial sections of the embryo, and then studying the sections under the microscope and drawing what he saw. He worked from dawn to dusk; in later years he wrote of his excitement, in those days, of seeing the brain, the backbone, the eyes, and the heart forming themselves before his eyes. He wrote: "I could hardly tear myself away from this self-imposed task. I can still recall the thrill as I saw, what had not then been described, the pituitary gland arising like a nephridium, which according to a theory I was already formulating it ought to do. I remember drawing a diagram on the laboratory bench before a group of fellow students to illustrate the idea of the evolution of the ductless glands (whose functions were then quite unknown) which was surging in my brain. It is an essential part of my pleasure in the work that I am now doing that it links directly with the happy labours of those days." What a vivid description this is of his own discovery of one of the "hidden mysteries of nature and science."

The Sympathetic Nervous System

Langdon-Brown was much influenced by Gaskell, whom he has described as "one of the greatest minds that ever adorned British physiology," and he said that an account of the sympathetic nervous system written before Gaskell was like writing a description of the circulation before Harvey. Speaking metaphorically, in those days more than one chapter was being written in the new Book of Physiology, and the contributors were collected by Michael Foster, who had a genius for choosing his men. Gaskell wrote the first chapter by his researches on the innervation of the heart; he laid the foundation on which modern cardiology is built. In the second chapter he showed that the nerve fibres which flowed from the spinal cord into the sympathetic chain were of smaller calibre than the nerves to the skeletal muscles, and by this standard he was able to show that there were fibres with visceral functions in the cranial and sacral nerves. J. N. Langley, with much help from Hugh K. Anderson, showed by his nicotine method that these small medullated fibres ended round cells in one or more sympathetic nuclei from which a new non-medullated fibre passed to its ultimate destination. Langley gave us a plan of what he called the autonomic nervous system, and he showed that it consisted of two parts—namely, the sympathetic and the parasympathetic—while Gaskell showed that when these two parts were distributed to the same structure their function was antagonistic.

Langdon-Brown was interested at once in the close connexion of the sympathetic nervous system with the ductless glands, and in his Croonian Lectures in 1919 he quotes Gaskell verbatim in his account of the evolution of the suprarenal glands. It is a curious story of chromaffin cells, which appear to originate in the central nervous system, and in the segmented worms they remain there. In evolution the sympathetic cells emigrate from the central nervous system into outlying nuclei accompanied by the chromaffin cells. Gaskell wrote: "The evidence of embryology and comparative anatomy thus points strongly to the conclusion that the sympathetic nervous system arose from the nerve cells containing adrenalin . . . and that when these cells left the central nervous system to become peripheral they

left not as single cells but as two separate cells, one of which contained all the adrenalin and formed the chromaffin system, and the other the nerve cells of the sympathetic system of the vertebrate."

Since then it may be that a comparable phenomenon has been discovered in regard to two groups of nerve cells in the hypothalamus—namely, the supra-optic and paraventricular nuclei. These two nuclei are a single mass of cells in submammalian vertebrates; in man they are distinct, but they have the same peculiar cytological characters. It has been shown by anatomists that these nerve cells may contain droplets of colloidal material in their cytoplasm. It seems that these small droplets may later coalesce into larger globules, which are extruded into the intercellular ground substance and taken up into blood vessels. It is noted that these two nuclei are permeated by an exceedingly rich capillary network, which, says Le Gros Clark, from whom this description is taken, suggests a high grade of metabolic activity. This is not yet proved physiologically, but the comparison with the origin of the cells of the suprarenal medulla from nerve cells in the spinal cord is evident, and so knowledge advances and the ball passes to and fro between physiologist and anatomist, and now in neuropsychiatry the biochemists and physicists are making their contribution to the game.

It was the close connexion of the hypothalamus with the pituitary and the importance of the pituitary gland in its effect on the function of other ductless glands that led Langdon-Brown to name the pituitary gland the "leader of the endocrine orchestra"; and in all his teaching as a clinician in later years he realized the close integration of function of the sympathetic nervous system and the ductless glands.

Psychology

The advance in our understanding of functional disorders has been so rapid in recent years that it is difficult to realize the darkness and fog that enveloped the subject of psychoneurosis 40 years ago, when Langdon-Brown began to apply his knowledge of the autonomic nervous system and ductless glands to the elucidation of neurotic behaviour. At that time psychologists were regarded as cranks and the average reaction to psychoneurosis was one of antipathy or disdain. I can illustrate this attitude of mind from my own experience in the examination for membership of this College in 1914, before the outbreak of war. As I entered the room for the viva voce examination I found the President sitting at the head of a large table and at the same table were the members of the Board of Censors. I was invited to take an empty chair on the President's right. The first and, as it turned out to be, the only question put to me by this distinguished company of Fellows of the College was asked by the President as soon as I had taken my seat: "Tell me, Dr. Evans, what diagnosis you would make in the case of a woman who had had her appendix removed for abdominal pain and later her gall-bladder removed for the same reason, and who during the next few years had no less than four abdominal operations for the division of adhesions?" After I had made a number of diagnoses, all of which I feared were futile, the President, seeing that I was nonplussed, said to me in a kindly way, "You have a lot to learn, Dr. Evans. This woman was suffering from Cheirurgophilia. It is a common complaint, Dr. Evans."

There were several reasons that led Langdon-Brown to develop an interest in psychology. He was mindful of Hippocrates' injunction to examine the whole of the patient. He realized that this required more than the simple physical examination that he had been taught by Dr. Gee, and that it involved the consideration of the patient's whole attitude to life, both past and present, and his adjustment to his environment. In the second place, he was influenced by his friend Dr. W. H. R. Rivers, who was brought from St. Bartholomew's to Cambridge by Michael Foster in 1893 to lecture on the physiology of the special senses. Rivers was a member of the expedition to the Torres Straits organized by Dr. A. C. Haddon, and Langdon-Brown remarks that the party went out as physiologists and returned psychologists. Here, then, was a man of high scientific reputation and unimpeachable integrity who found his true mission in life in the treatment of soldiers suffering from war neuroses. In the third place, Langdon-Brown had had experience of war as senior physician in the Imperial Yeomanry Hospital, Pretoria, in the South African War. But the first world war was different. Much larger numbers were involved and the hardships and terrors of war were greater, and this brought him to realize the importance of emotional disturbance in causing physical ills. He found that physiological principles and facts could be as well applied to war neuroses and later to civilian neuroses as to the physical ills which he had chiefly studied up to date.

In his inaugural lecture as regius professor of physics in the University of Cambridge, Langdon-Brown gives a bird's-eye view of the relation of emotion to organ function, and explains in simple language how emotional stress may cause symptoms of disease. The following illustrates his approach to one aspect of this large subject. "When under conditions of modern life emotion is dissociated from the movement it should evoke under more primitive conditions, the sympathetic disturbance may continue. The mobilized army which is not allowed to fight the enemy becomes a danger to its own country." The same notion must have been in the mind of William Blake when he wrote: "Better murder an infant in its cradle than nurse unacted desires." Then, expanding his thesis, Langdon-Brown continued: "Nervous impulses tend to run along accustomed channels. The exciting cause may long have passed from the realm of consciousness, but its effects may continue. Designed for an intensive preparation for action or defence, the sympathetic response may be dissociated, perverted, or prolonged, with serious effects on the individual. The pressure of the blood or its sugar content may be kept too high, the digestive processes in stomach or intestines may be inhibited, from purely emotional causes, yet ultimately leading to organic changes in structure." This is an interesting passage because it introduces two ideas—namely, organ habit and functional disorder as the cause of change in structure.

In 1938, when President of the Medical Society of Individual Psychology of London, Langdon-Brown gave his own answer to how he became interested in medical psychology. In this address he dealt with Adler's contribution to general medicine. He first referred to Adler as having linked psychoneuroses with organ inferiority, thereby enabling orthodox medicine to join hands amicably with the new psychology; and he said that Adler's main theses had been the early formation of a style of

life, the significance of each child's position in the family hierarchy, the importance of knowing the goal towards which the individual is consciously or unconsciously striving, and the vital necessity for co-operation with others. From Adler, Langdon-Brown passed to Jung, attracted by Jung's wider and more far-reaching conception of the human mind.

Teaching

Langdon-Brown was a great teacher not only of clinical medicine to students within the walls of St. Bartholomew's Hospital but also to the world at large in many lectures and addresses that he gave to important medical, scientific, and literary societies.

Professor V. H. Mottram, who has had forty years' experience of teaching physiology—a Cambridge man and well known to many who are here to-day—in a broadcast talk on education given three years ago provided an insight into the make-up of a good teacher or educator. What he said applies so truly to Langdon-Brown that I will quote some of his words: "It is axiomatic," said Mottram, "that education should set out to develop those qualities which have enabled man to evolve from and dominate the kingdoms of plants and animals. At the head of the list are the faculties which we can loosely term spiritual: awe in the presence of the sublime; reverence for the true, the good, and the beautiful; worship of the numinous (which means of or belonging to the deity, the presiding power or spirit). . . . Next comes the capacity for making use of the stored wisdom of the past, oral and written. This needs language. . . . No one incapable of the accurate use of language can think; accurate language—English—spoken, written, or declaimed, prose or poetry."

Langdon-Brown had all this, and it was born in him. Both in discourse and in writing he made frequent reference to the spiritual component of human nature, and in all that is and is to be he realized the handiwork of the Great Architect of the Universe. Thus when as an undergraduate he embarked on the study of embryology he was completely thrilled. For him it was "a lovely science." In his own words, "Wonderful beyond anything I had hitherto learned was the marvellous energy of the fertilized cell; the Unseen Potter moulding the growing protoplasm deftly according to a preconceived plan." Of the three great experimental psychologists, Freud, Adler, and Jung, he was most in sympathy with Jung, because, as he said, "Jung of all men is best qualified to reconcile life with spiritual values." And he went on to say, "Man is more than a bundle of conditioned reflexes and behaviourism, and can never remain satisfied with psychology without the psyche. It has been suggested that it would be well to study the simpler Adlerian philosophy of social-cooperation on the way to the study of Jung, for with Jung lies the future of psychology that can best explain and meet the deepest emotional needs." It was this feeling for the sublime which took him away from the material grandeur of Roman antiquities and led him to find a deeper satisfaction in Greek art and mythology.

In the nineteen-thirties his visits to Rome ceased. He said that he had come to dislike the fact that the most striking landmarks of the city were memorials to the individual. That the Roman, hating the transience of life, demanded some projection of the ego. Thereafter he spent more time in Athens and in the Greek islands.

finding far greater appeal in the reticence of the sceptical and modest Greeks—with their “whispers of a sigh to greatness.” In Grecian art he found his ideal of created beauty, and his description of a statue, one of several dredged up off the coast of Greece, which he watched being carefully cleaned in the Museum of Athens, records his feelings on this occasion. “It was an exquisitely beautiful figure of a boy, perfect in every respect except for the palm of his left hand. His right arm was uplifted and he appeared to be gazing with wonder and delight at something which has now vanished, but once rested on that left hand. It has been suggested that this was a lyre which the boy had struck and that he stood, enchanted by the music he had created. . . . For me,” he wrote, “it was a symbol of the recurrent wonder and delight that different generations have experienced on discovering again the treasures of the Greek mind which more than once have sunk beneath a sea of indifference and neglect.” I have the permission of Freda Langdon-Brown to quote from a letter she wrote to me that these her husband’s words “speak so clearly to me of him and his love of beauty; and of that enchanted and enchanting quality of awe and wonder which was his to hold and share to the end of his life.”

Accurate Use of Words

As to the second qualification for a lecturer or educator, Langdon-Brown was equally well endowed. An accurate use of words is of course essential to clear thinking; this is brought home to us by the Greek word *λόγος*, which means both a word—that is, the outward form by which an inward thought is expressed—and the inward thought itself. Thus *λόγος* comprehends both *ratio* and *oratio* in the Latin language. But the word, the spoken or the written word, means much more than this to us. It expresses at once both thought and feeling, it expresses the whole range of feeling, mood, emotion, and affect—*affect* means mental disposition, which is the essential basis of personality. And so for Langdon-Brown the accurate use of words was an expression of absolute sincerity and truth, which were hall-marks of his character, and I can illustrate this by a simple conversation as we walked to his home in Cavendish Square after a meeting. It was in 1935, soon after Hitler had arrived on the world’s stage. I asked Langdon-Brown what he thought of Hitler. His answer was, “I do not trust him; he does not speak the truth. I believe the words in the Bible, ‘In the beginning was the word, and the word was with God, and the word was God.’ The same was in the beginning with God.’ You can’t get away from that,” he added, meaning the sanctity of the spoken word and the sacrilege of lying.

His literary education began when he was very young. He described his father’s study as an enchanted room, lined to the ceiling with books: volumes of old topographical prints his father had collected; editions of *Pilgrim’s Progress* in sixty languages; Bunyan’s cabinet, walking-stick, and mug; Gibbons’s *Decline and Fall*; Smith’s *Dictionary of Greek and Roman Biography and Mythology*; Chaucer’s and Shakespeare’s works. Here he sat, his legs too short to reach the ground, a reading-desk in front of him, reading while his father wrote. It recalls Wordsworth’s lines:

“And books are yours
Within whose silent chambers treasure lies
Preserved from age to age.”

Langdon-Brown had a receptive mind and a retentive memory. He had great knowledge and a store of wisdom to impart. He did me the honour of asking me to collaborate with him in writing the sections on diseases of the kidney and vasomotor neuroses in Price’s *Text-book of Medicine*, the first edition of which was published in 1922. We continued together in this work, through seven editions, until he died. We used to work together after dinner at night. We worked late. He never seemed to tire, and it was remarkable that he always had the words and phrases immediately at hand to express what was in his mind, whether for construction of something new or alteration of what was already written. Dr. Hilton has told me that he had the same experience of his quick brain and facility of expression when they worked together on the later new editions of the *Physiological Principles in Treatment*. It is fitting for me here to pay tribute to the generosity of his character, his patience and forbearance, and his great kindness.

Contribution to Literature

Langdon-Brown’s contribution to English literature is his book entitled *Thus We Are Men*. It is largely a collection of lectures and addresses which he gave at various times, and it is dedicated to his wife (“my collaborator”). In this book the reader will find an account of some viewpoints of modern psychology and the author’s own experience of their application to the practice of clinical medicine. It is a wonderful book to read: it reflects so much of a highly cultured mind, and it contains a number of the author’s original ideas. One of these concerns the psychology of authorship, for it was Langdon-Brown’s idea that literary criticism would be a more living thing if it were realized that, in works of imagination, a revelation of the working of the author’s unconscious mind is to be found in his writings, although, as he remarks, it is not permissible to treat the writings of an author as if they were strictly autobiographical. He was much interested in Barrie’s works, and in a chapter entitled “Myth, Phantasy, and Mary Rose” he interprets the whole genesis of Peter Pan in terms of a mother-fixation complex. This is Barrie. If, then, Sir Walter Langdon-Brown’s thesis is applied to his own writings, the reader is arrested by his account of his meeting Barrie. “The only time I had the pleasure of meeting Barrie,” he wrote, “I mentioned the idea that Lob was Peter Pan grown old. Barrie replied, ‘That’s good; how did you find it out?’ I replied, ‘My wife told me.’ ‘She must be a remarkable woman,’ was his comment.” And so he lets his conversation with Barrie tell the world that the theme of this chapter was given him by his collaborator.

Thus We Are Men was published in 1938. An American writer, Dr. Alvarez, came across this book ten years later and published a review of it in *Gastroenterology*. He wrote of its being “full of inspiration,” and of its author he said: “It is immediately evident that he was not only a master of the practice of medicine but also one of the best educated of the world’s physicians.”

In reading the works of Langdon-Brown one is repeatedly impressed by the soundness of his views and his anticipation of advancing knowledge. I will give two illustrations in support of this statement. In the first Suckling Memorial Lecture, delivered at University College Hospital in 1939, the subject of which was visceral symptoms in emotional states, Sir Walter Langdon-Brown discussed the connexion between

emotional expression and the visceral nervous system. "Mental activity," he said, "naturally largely depends on the stream of afferent impulses pouring in on all sides." He then quoted from Professor Michael Foster as follows: "We can hardly doubt but that volitional and other psychical processes would soon come to a standstill and consciousness finish" in the absence of these afferent impulses. Michael Foster had quoted a remarkable case of a man who was blind in one eye, who was totally deaf, and who had general cutaneous anaesthesia. His sole remaining tie with the outside world was through the other eye, and if this were closed he simply went to sleep.

In 1947, in his Lumleian Lectures, Dr. Purdon Martin reported a comparable case of a woman aged 56 who suffered a cerebral haemorrhage at the level of the middle of the pons which spread horizontally and involved the whole median fillet on either side and the adjacent lateral fillets and other auditory structures, as well as the sixth nuclei and the right facial nerve. This lesion had been diagnosed correctly during life. When one median fillet was involved the woman was drowsy; when the other side became involved it was impossible to keep her awake. She had become deaf too, and so, writes Dr. Martin, when she closed her eyes all her channels of reception of impressions from without were interrupted (except smell, which was not tested), and in these circumstances she fell into a deep sleep. And Dr. Martin asks, "Is it awareness of the body that is essential for consciousness?" and he concludes that if nearly all the sensory pathways are interrupted the activity of the cortex is greatly depressed or is abolished.

Langdon-Brown more than once refers in his writings to the difference in relation of cortical *vis-à-vis* hypothalamic activity in most animals as compared with man. He writes: "Man is essentially an image maker: it is his human prerogative. Thus in most animals, who act from what we call instinct, action follows on stimulation of the perception mechanism with almost chemical swiftness and certainty; in man the nervous system is more complicated; perception is not instantly transformed into reaction; there seems to be an interval for choice."

Recent anatomical research has perhaps found the nervous pathway that makes it possible, as Langdon-Brown said, for the human being to think again. Nerve impulses from most, if not all, of the cerebral cortex connect with nerve cells in the temporal lobe. They are relayed from there to a subcortical centre called the hippocampus; it is a massed battery of cells whose fibres travel together in a well-defined bundle to the hypothalamus, the head ganglion or centre of the involuntary nervous system. In most animals nerve impulses from the cortex reaching the head ganglion or hypothalamus in this way would lead to an explosion of involuntary activity such as rage, or fight or flight. But in man and the higher mammals these involuntary mechanisms are not necessarily stimulated to activity by these nerve impulses, and it may be because they are immediately relayed back to the cortex—that is, to the frontal lobe. Professor Le Gros Clark in his contribution to *Perspectives in Neuropsychiatry*, edited by Dr. Derek Richter, asks: "Can this possibly provide the basis for the development of the more intelligent type of behaviour involving more continuous cortical processes and characterized by rational deliberation, rather than the instinctive type of behaviour in which the first

results of cortical activity are immediately expanded in impulsive actions of a purely emotional character?"

The anatomical connexions of the prefrontal cerebral cortex with the hypothalamus had occurred to Langdon-Brown already thirteen years before as the possible pathway along which psychical activity expressed itself in physical symptoms.

Royal College of Physicians

Langdon-Brown made valuable contributions to the life and work of this College. He was elected a Fellow of the College in 1908, and gave the Croonian Lectures entitled "The Role of the Sympathetic Nervous System in Disease" in 1918 and the Harveian Oration in 1936. It was in 1931 that he served as Senior Censor, and it seemed to many Fellows of the College that he might in due course be elected our President.

Any attempt to portray the life and character of Langdon-Brown would be incomplete without a reference to an unhappy time in his life which lasted over a period of years. There is, I feel, some truth in the idea of salvation through suffering, in the idea that tribulation brings at least a sensation of the power of God and perhaps a better understanding of His purpose. It has seemed to me that the text on Rahere's tomb in the church of St. Bartholomew the Great actually applies to these years in the life of Langdon-Brown; the words are those of the third verse of the 51st chapter of the Book of the Prophet Isaiah, "For the Lord shall comfort Zion: he will comfort all her waste places; and he will make her wilderness like Eden, and her desert like the garden of the Lord." In due course joy and gladness came again into the life of Langdon-Brown, and he pursued his objectives with renewed vigour and enthusiasm.

Regius Professor

In the summer of 1932 the Prime Minister offered Langdon-Brown the chair of regius professor of physic at Cambridge University. This appointment brought him great happiness as well as honour, because it meant his return to his "beloved alma mater," his affectionate term for Cambridge. It is one thing to be appointed regius professor of physic and it quite another to find a way into the social life of the university and so become one of those who belong to the place. The door was opened to him by Corpus Christi College, who offered him a professorial fellowship. This invitation was made in an exceptional way, for, so far as is known, he is the only Fellow of the College who has been thus invited "unseen by the Fellows of the College." He found great social interest here in dining with the Fellows, his room in the College and the Master's Lodge always hospitably open both to him and to his wife. He received the honour of knighthood in 1935, and on February 20 Sir Walter Langdon-Brown received the accolade from his Majesty King George V.

The years of his appointment as regius professor were fully occupied with work of a varied kind. His inaugural lecture as regius professor, of which chair he was the twentieth holder in 392 years, was of the highest order. He gave a number of lectures and addresses in addition to set courses of lectures for the university. He was an examiner at Cardiff and Sheffield Universities, and in the National University of Ireland, and he conducted the Cambridge M.B. examination in medicine. In 1935 his retirement under the age limit for

professors came all too soon. He left Cambridge with deep regret, full of gratitude for the kindness and friendship he had received from Corpus Christi College and from that College of his young enthusiasm, St. John's College, whence came the invitation which he received and accepted with great pride—to give the Linacre lecture in 1941. He returned to Cambridge for the last years of his life, and he was occupied till the end in writing *Some Chapters in Cambridge Medical History*, published in 1946 by the University Press.

Conclusion

Sir Walter Langdon-Brown died in 1946 at the age of 76 honoured by all and loved by his friends, and holding the devoted affection of the nearest and dearest to him. He used to speak with pleasure and satisfaction of the survival of the institutions, of his beloved university in particular, throughout future generations. I would like to speak of the survival of his life's work, the central thesis of which is best defined in his own words. "As we are animals we conform to biological laws. Our future evolution physically is improbable and mentally unlikely. Therefore only a psychological evolution remains. This necessitates co-operation, not merely instinctive as with bees and ants, but intelligent and voluntary. Now we, like all animals, carry with us vestigial traces of our past ancestry, not least in our mental processes. To develop psychologically we must understand ourselves, and it should help us to do so if we can find ways to investigate those hidden depths in our minds from which we draw our impulses."

Psychology has for some years been chiefly concerned in looking back, and it has been a preoccupation of psychologists to search out the origin of thoughts and feelings. This has been a contribution to knowledge as was Charles Darwin's work on the origin of the species. Langdon-Brown asks us to look forward and to find ways—new ways—to investigate the hidden depths of the human mind. Godwin Baynes, speaking of a moral act or response being invariably individual in origin, said, "A moral feeling can be imparted to a community, but its source is in the solitary individual soul." The same holds good for original ideas; they too have their origin in the individual mind. The work and teaching of Sir Walter Langdon-Brown was spread on so large a canvas that it must be viewed from a distance to be seen as a whole. His contribution to medicine was no discovery of factual knowledge, nor was it the presentation of some ideas; it was a wide conception which has given a fresh inspiration and a new direction to the understanding of the human mind.

According to the Swedish International Press Bureau the Swedish Medical Association has agreed on a *Codex Ethicus Medicorum* embodying 15 rules of ethics for medical practitioners in Sweden. Simultaneously a new set of rules for medical specialists has been agreed upon. These two briefs of rules aim at maintaining the high standard of Swedish physicians. They contain instructions on the relationship between the doctor and his patient, and clearly define the duty of the physician towards the preservation of human life, professional secrecy and ethical points about monetary reward, publicity, etc. It is stressed specially that a physician should refrain from advertising himself or his work in an importunate or flagrant way and not draw inappropriate attention to his person when giving information to the Press.

GENERALIZED OSTEOARTHRITIS AND HEBERDEN'S NODES

BY

J. H. KELLGREN, F.R.C.P., F.R.C.S.

AND

R. MOORE, M.R.C.P.*

(From the University Rheumatism Research Centre at the
Royal Infirmary, Manchester)

Osteoarthritis is usually considered to result from degenerative changes in the articular cartilage and other joint structures which occur to some extent in most individuals with advancing age, but which may occur prematurely in joints subjected to abnormal wear and tear from some special occupational stress or as a result of faulty joint mechanics.

Premature degeneration of a severe nature and more rapid in evolution occurs in joints in which the articular cartilage has been damaged by trauma, infection, or avascular necrosis of the underlying bone. Rapid degeneration may also occur in joints deprived of the protective reflexes afforded by normal pain and proprioceptive sensibility.

Although the degenerative arthritis of old age may affect many joints, the premature degeneration resulting from previous damage by trauma, etc., tends to affect only one or at the most a few joints, because the degenerative process is secondary to these causative factors, which as a rule are operative in only one or a few joints and, since the degenerative process is slowly progressive, the resultant disability also tends to be slowly progressive, though acute painful incidents following trivial injury or unusual stress may be superadded.

The clinical and radiological features of degenerative arthritis are well known, and patients with this condition are seen with great frequency, particularly in orthopaedic clinics; but in clinics dealing largely with rheumatic disease one often sees polyarthritic patients in whom the joint changes in the later stages resemble those of degenerative arthritis, though they differ somewhat in that they often have a rather acute spontaneous onset. Furthermore, these patients tend to present a definite pattern of joint involvement characterized by affection of the distal interphalangeal joints of the fingers, and the first carpo-metacarpal joints in the hand, the great toes, and first tarso-metatarsal joints in the feet, the interfacetal joints of the spine, the knees, hips, and other limb joints. These patients also present certain other characteristic clinical and radiological features which differ from those found in classical degenerative joint disease on the one hand and polyarthritis of the rheumatoid type on the other, and we have come to classify these cases under the heading of primary generalized osteoarthritis, which we consider to be a distinct clinical entity.

More than 150 years ago William Heberden recognized the fact that the nodes so often seen over the distal interphalangeal joints of the fingers represented a condition distinct from either gout or rheumatism, and in 1805 Haygarth described 34 cases of multiple arthritis associated with Heberden's nodes which he classified separately under the heading of "nodosity of joints." A

*Nuffield Fellow in chronic rheumatism.

polyarticular osteoarthritis was also mentioned by Adams (1857) and Charcot (1881). In more recent years Cecil and Archer (1926), while classifying 182 cases of degenerative arthritis attending their rheumatism clinic, noted that only 20 were of the classical monarticular type and only 17 of the senile type, while 145 were polyarticular and usually associated with Heberden's nodes. Because this latter group was largely composed of middle-aged women they considered this form of arthritis to be "menopausal." Francon (1950) also describes a generalized form of arthritis associated with Heberden's nodes.

On the other hand, Stecher (1948) considered these nodes to be a distinct entity, although he did note a tendency to involvement of other joints (Stecher, 1946b); but in this connexion it must be remembered that Stecher was engaged in a genetic study of the incidence of asymptomatic nodes in the general population, and he was less concerned with the more severe forms of this condition which send the sufferer to the rheumatism clinic. Stecher, however, made a most valuable contribution when he separated the post-traumatic type of node from the idiopathic inherited variety.

Interest in the question of whether Heberden's nodes are associated with generalized arthritis has been stimulated in this department because a routine examination of all the joints of the body is carried out in every patient attending the clinic, even though they may complain only of a single joint, and this routine has allowed us to recognize more clearly the patterns of joint involvement characteristic of the various forms of articular disease, and in particular that associated with Heberden's nodes.

The following description of what we consider to be primary generalized osteoarthritis is based on the experience of 391 cases of osteoarthritis taken from a total of 1,813 cases of arthritis of all types seen in this department during the three years preceding 1951. In addition we have made a detailed analysis of the 196 cases of osteoarthritis seen during the year 1950. Of these, 120 had either Heberden's nodes or arthritis of the first carpo-metacarpal joints or both; 20 were of the classical monarticular degenerative type, and 56 were classed as miscellaneous because, although their arthritis was polyarticular, the characteristic involvement of the hands was not found.

Sex and Age

In the first instance we will describe the features of those cases with characteristic involvement of the hand joints. The condition is found predominantly in middle-aged women; thus of the 120 analysed cases 110 were in women, whose ages at the onset of the disease varied from 35 to 73, with a mean of 52 years. There was, however, no accurate correlation with the menopause, and in 22 cases the arthritis began while the menses were still normal. The age of onset in the 10 men ranged from 20 to 63, with a mean of 50.7 years.

Pattern of Joint Involvement

This is one of the most characteristic features of primary generalized osteoarthritis. Thus of the 120 analysed cases 103 had Heberden's nodes, 79 had arthritis of the first carpo-metacarpal joints, and 62 had both. In a few cases the arthritis also affected the joint between the scaphoid and the multangulum majus, but the rest of the carpus and the metacarpo-phalangeal joints which are so characteristically affected in rheuma-

toid arthritis were usually spared, only very slight changes in these joints being found in 19 cases. On the other hand, the proximal interphalangeal joints were often severely involved, these joints being affected to some extent in 49 cases. The joints of the feet were affected in 50 cases, and in 40 of these the metatarso-phalangeal joint of the great toes was the one maximally affected.

In 22 cases there was also some involvement of the lateral metatarso-phalangeal joints, but the changes in these were always less than in the great toe, which is the reverse of what is found in rheumatoid arthritis; there was also some tarsal arthritis in 20 cases, and in several the joint between the first cuneiform and the first metatarsal was markedly affected. The knees were affected in 64 cases, nearly always bilaterally, and the hips in 36, while the spine was affected in 57, being the most frequent part to be involved after the hands and knees. The remaining joints were but rarely affected, and usually only to a lesser degree in those florid cases in which nearly all the joints of the body were involved.

Nature of Joint Lesion

Each affected joint tends to pass through two stages: an initial relatively acute phase during which the joint may be warm, red, and exquisitely tender; and, some months later, a chronic phase characterized by bony outgrowths around the joint margins. In the acute phase the joint is usually slightly swollen and may contain a small effusion, this excess fluid being particularly noticeable in the knees. The massive soft-tissue swelling and synovial thickening characteristic of many cases of rheumatoid arthritis is, however, not seen. During this initial acute phase spontaneous pain may be very troublesome. It often comes in severe spasms, particularly at night-time, and waking the patient in the early hours. When the finger-joints are severely affected and the skin over them becomes reddened and tender the pain acquires a characteristic burning, tingling, and bursting quality, and the patients place their hands outside the bed to obtain relief. This type of pain is particularly evident in those cases in which small cystic swellings form over the finger-joints, finally to burst through the skin, discharging a little glairy fluid (Fig. 1). More usually the pain is of the deep aching type, and is not well localized to the joints, often spreading widely up and down the limbs. This deep pain is also markedly aggravated by cooling the part, and these patients avoid cold water and dread exposing their hands in cold weather, although vasospasm is not a feature of this condition.

During the acute phase a few minutes of arterial occlusion produced by a cuff on the arm will cause a rapid and severe increase of pain: in this respect the pain resembles that of acute suppurative lesions such as whitlows (Addis, Jepson, and Kellgren,

FIG. 1.—Early node with discharging cyst (Case 1).

1950), and indeed two of our more acute cases were initially thought to be suffering from pulp-space infections of the finger. When a large joint such as the knee is affected in this acute manner the pain may be very severe, and the condition is not unlike that of a low-grade suppurative arthritis, though the constitutional disturbance usually associated with infection is absent.

After a period of several months the acute phase subsides and the clinical signs of inflammation disappear, giving place to the chronic phase, which is characterized by massive bony outgrowths around the joint margins. At this stage there is little pain, and, in spite of the unsightly deformity and gross radiological changes, the joints often retain a fair range of movement and function

progresses first one joint becomes involved and then another, each joint passing through a more or less painful phase and going on to bony enlargement, which is relatively painless.

By no means all the cases present with an onset which is acute enough to resemble a pyogenic process; indeed, only 21 of the 120 cases had incidents of this type in one joint or another, the more usual story being one of a sub-acute or even gradual onset. Nevertheless, a more or less

FIG. 2.—Multiple nodes and enlargement and adduction deformity of first carpo-metacarpal joint (Case 2).

is largely restored; thus permanent crippling very rarely ensues. The appearance of the hand in a more advanced case is shown in Fig. 2. Note the bony ridges over the terminal joints of the finger, the enlargement and deformity of the proximal interphalangeal joints, and also the bony enlargement, partial subluxation, and adduction deformity of the first carpo-metacarpal joint, giving the hand a curious squared appearance.

Fig. 3 shows the hand of a very advanced case. Although in this case nearly all the joints show bony enlargement the characteristic appearance is still retained. The condition in the hand is quite characteristic and easily recognized, but in the less accessible joints bony enlargement is less readily appreciated, and in the spinal articular processes it may be easily overlooked. Thus in the spine there is often a history of severe back pain and disability lasting several months followed by partial recovery which leaves the patient with only slight limitation of spinal movement, particularly in side flexion and rotation, and it is only by radiography that the marked bony outgrowth on the articular facets and spinous processes can be demonstrated. As the disease

FIG. 3.—Advanced case with bony enlargement of all joints.

painful initial phase in each affected joint is the rule in the more severe cases. The characteristic course of the disease is well illustrated by the following case histories.

Case 1

A housewife aged 56 had noticed increasing deformity in the distal and proximal interphalangeal joints of the hands accompanied by much pain for 15 years. During this time acute joint incidents had been noticed, in which first one and then another of the distal interphalangeal joints of the hands would become acutely swollen, painful, and red; and a cystic swelling would appear at the lateral aspect of the joint. This became so painful that she evacuated it with a needle, after which the pain would subside for about a fortnight, to recur as the swelling filled up again. Gradually the swelling became painless, stopped discharging, and left a hard bony knob at the base of the distal phalanx. This series of events then occurred in another distal interphalangeal joint over a period of six months before the discharge finally ceased. For four years she had been troubled by pain and stiffness in the left ankle and had had a goitre from the age of 14 years. The menopause occurred at 46. One sister had Heberden's nodes.

On examination she was seen to be a healthy woman weighing 8 st. 12 lb. (56.2 kg.). A small diffuse goitre was present. There was no clinical evidence of visceral disease. The hands showed large tender Heberden's nodes, and enlargement, tenderness, and limited movement of most of the proximal interphalangeal joints and both first carpo-metacarpal joints. There was also some swelling of the left ankle, and its movements were slightly limited. The distal interphalangeal joint of the right middle finger was very swollen and an acutely tender cystic swelling was present on the lateral edge of the joint, which had discharged a yellowish jelly-like fluid. The erythrocyte sedimentation rate was 35 mm. in one hour, the haemoglobin 84%, and the white blood cells 5,700 per c.mm.

Case 2

A housewife aged 65 had first developed pain and swelling of the distal interphalangeal joints and the first carpo-metacarpal joints 12 years ago. Acute episodes had occurred in the distal interphalangeal joints, lasting months and leaving Heberden's nodes in their wake. At this time the shoulders also became stiff. Eight years ago the knees had become swollen, painful, and stiff, and after a further four years the lower part of the back had become painful. She had been gaining weight for about four years. She had pernicious anaemia at 57 years and had passed a tapeworm at 63. The menopause occurred at 54. There was no family history of rheumatism.

On examination she was seen to be a robust woman weighing 10 st. 12 lb. (69 kg.). There was no visceral disease. Painful Heberden's nodes were present on all the fingers; both first carpo-metacarpal joints were painful, swollen, and limited, especially the left one; and both knees were slightly swollen and painful, and contained effusions. Movement in the right was from 5 to 110 degrees flexion, while that in the left was normal. She attended monthly for observation, and in the third month suddenly developed acute pain in the right knee, which became very much more swollen owing to increase in the effusion; the overlying skin was reddened, and movement was reduced to 5 to 70 degrees flexion. The joint had, in fact, the appearance of an acute arthritis, and she took to her bed for a fortnight, by the end of which time the pain began to subside. A plaster leg cylinder was then applied and she was encouraged to use the leg. After six weeks the plaster was removed, as the knee had returned to its previous condition; its movement was again what it had been before the acute incident. When she was first seen the erythrocyte sedimentation rate was 15 mm. in one hour; it rose to 26 mm. during the acute joint incident. The haemoglobin was 86% and the white cell count 5,300 per c.mm.

Case 3

A housewife aged 60 had noticed pain and swelling of the first carpo-metacarpal joints of both hands with weakness of the grip six years ago. Several months later the distal interphalangeal joints of the middle fingers of each hand became acutely swollen and painful, and a cystic swelling appeared on the dorsum of the middle left distal interphalangeal joint which discharged a yellowish fluid intermittently for a considerable time. The acute swellings subsequently involved the distal interphalangeal joints of the other fingers of both hands, eventually becoming painless over a period of three years, leaving bony swellings typical of Heberden's nodes. Four years ago the right hip gradually became troublesome: she noticed stabbing pains in the thigh on walking, the hip gradually developed a flexion deformity, and she suffered from severe pain in the groins, particularly when lying in bed. At this time walking became difficult.

Eighteen months ago she sought surgical advice, and, after a right subtrochanteric osteotomy had been performed, was nursed in a double hip spica for the next five months. On removal of the plaster it was noticed that the left hip and lumbar spine had become stiff and painful. Since removal

of the plaster the knees have been painful and have gradually lost their range of movement, and she is now only able to walk a few yards with the aid of sticks. Her general health has remained good throughout, and there has been no weight loss. The menopause occurred at 53 years. There was no family history of rheumatism.

On examination she was seen to be a pale slim woman in good general health but distressed by pain on movement in both hips. Her blood pressure was 210/110, but there were no clinical signs of visceral disease. Pronounced Heberden's nodes were present on the fingers and there were marked bony enlargement and deformity of the first carpo-metacarpal joints and some bony enlargement of the proximal interphalangeal joints, but the wrist movements were full and painless. Dupuytren's contracture of the fourth and fifth fingers was present in the right hand. The knees were slightly swollen and tender, and their movement was moderately limited. There was bony enlargement of the first metatarsophalangeal joints of the feet, with some limitation of movement. Examination of the spine revealed a flattening of the lumbar curve and almost complete absence of movement in the dorsal and lumbar regions. The right hip was completely fixed in 10-degrees flexion, while the left hip was capable of movement through 15 degrees of flexion. The erythrocyte sedimentation rate was 13 mm. in one hour, the haemoglobin 98%, and the white cell count 4,400 per c.mm.

Other Clinical Features

In spite of the acute and apparently inflammatory nature of the initial arthritic process we have not observed any constitutional disturbance in these patients. Thus weight loss, which is such a feature of rheumatoid arthritis, was not observed, and the blood picture was not abnormal. On the other hand, the sedimentation rate, estimated by the Westergren method, was often somewhat raised; thus out of the 112 cases for which figures are available 66 had an E.S.R. of under 20 mm. in the hour. In 38 cases the E.S.R. was between 20 and 40 mm., but in only 8 cases was it over 40 mm. The mean value for the whole group was 19 mm. This contrasts with the findings in our group of 20 cases of monarticular degenerative arthritis, in which the E.S.R. was less than 20 mm. in every case, the mean value for the group being 11 mm. The differential agglutination reaction, which is so often positive in rheumatoid arthritis (Rose *et al.*, 1948; Ball, 1950), was also uniformly negative in these cases.

Soft-tissue lesions, such as thickening of the bursae, and widespread involvement of muscles and fascia were not observed. The florid multiple tendon lesions so characteristic of rheumatoid disease (Kellgren and Ball, 1950) were also not observed in these cases, although in 13 of them a few small firm nodules could be felt in the flexor tendons of the hands. There was also no tendency to vasospasm or excess sweating; neither were there any cutaneous or eye lesions or characteristic visceral disturbances. Thus the disease process seems to be largely confined to the joints, and particularly the diarthrodial joints.

It has been suggested by Fletcher (1947) that both obesity and hypertension occur with unusual frequency in patients with osteoarthritis. On the other hand, Stecher (1946a) did not find any such correlation with Heberden's nodes. Among our 120 cases there were no patients who were grossly obese, and in only four was the systolic blood pressure over 200 mm., and in only two was the diastolic pressure over 120 mm. Thus neither marked obesity nor serious hypertension appears to be a feature of generalized osteoarthritis.

Radiological Changes

The x-ray appearances of the stage of bony enlargement conform to those of osteoarthritis. There is narrowing of the joint space, marked sclerosis of the subchondral bone, and florid bony outgrowths at the articular margins. The radiographs reproduced in Figs. 4-9 illustrate the changes seen in the various joints commonly affected. The combination of Heberden's nodes and arthritis of the first carpo-metacarpal joint is a most characteristic finding, and the enlarged views of these joints show the marked tendency to bony enlargement that is so characteristic of the later stages. The changes in the spine (Fig. 7) are peculiar in that the intervertebral disks remain relatively unaffected, while the articular facets and the neural arches, including the spinous processes, become enormously enlarged and sclerosed, so that "kissing spines" are often seen. Thus the spinal changes conform to the osteoarthritis of Collins (1949), who distinguishes between these changes and the osteophytosis of the vertebral bodies which so frequently accompanies degeneration of the intervertebral disk.

In the hips (Fig. 8) the changes are less distinctive. There is a general loss of joint space and the femoral head tends to become elongated; in advanced cases it becomes enclosed in a deep sclerosed acetabulum, resulting from marked overgrowth of the acetabular margin and not from protrusio acetabuli. In several

cases crumbling of the upper quadrant of the femoral head was noted in one hip, but in these instances there was a past history of significant trauma to the hip. In the knee (Fig. 9) the radiological picture is again fairly distinctive. There is marked narrowing of the joint space combined with rounded "molten wax" bony outgrowths at the articular margins and a marked absence of the sharp-pointed osteophytes so commonly seen in the

FIG. 4.—Whole hand, showing marked changes in terminal interphalangeal and first carpo-metacarpal joints: there are also slight changes in some of the proximal interphalangeal joints.

FIG. 5.—Enlarged views of advanced finger node. The most marked changes are seen in the lateral view.

FIG. 6.—Full-size view of first carpo-metacarpal joint showing much new bone formation.

FIG. 7.—Lumbar spine, showing marked enlargement of facets and spinous processes.

degenerative arthritis which follows injury.

Although the overall radiological picture is certainly that of osteoarthritis, in that narrowing of joint space, subchondral sclerosis, and marginal bony overgrowth are present, there are certain differences between the radiological appearances of primary generalized osteoarthritis and those of classical degenerative joint disease.

The Miscellaneous Group

On analysing the miscellaneous group of 56 patients who had polyarticular osteoarthritis but without Heberden's nodes or arthritis of the first carpo-metacarpal joints it became apparent that many of them presented features which we have come to regard as characteristic of primary generalized osteoarthritis, and it seems probable that further experience may justify the classification of many of these cases under the heading of generalized osteoarthritis; we are not yet, however, prepared to make this diagnosis in the absence of Heberden's nodes or arthritis of the first carpo-metacarpal joints. Furthermore, we fully recognize that there are many patients in whom degenerative arthritis of the terminal finger-joints may follow injury or unusual occupational strain (Stecher's traumatic nodes), and that arthritis of similar pathogenesis may affect the first carpo-metacarpal joint; but these cases are easily recognized, and have been excluded from the present investigation.

Treatment

In view of the large number of middle-aged women in our series and the fact that other workers have considered this form of arthritis to be menopausal; we carried out a blind clinical trial of oestrogen therapy. Twenty severely affected middle-aged women were selected, and were divided into two groups of 10, which were as evenly balanced as possible in regard to age, severity, and duration of symptoms, E.S.R., and number of joints affected. Mr. Lloyd, the hospital pharmacist, kindly provided us with two lots of indistinguishable tablets, A and B, one inert and the other containing 0.3 mg. of dienoestrol. These were administered in a dosage of one tablet three times a day for six months, 10 patients receiving

tablets A and 10 tablets B. The patients were seen monthly and were fully assessed before treatment and at the end of six months. Neither group reported any marked subjective improvement, and examination revealed a slight deterioration in both groups. Thus the grip measured by the method of Janus (1950) fell slightly in both groups. The E.S.R. rose slightly in both groups, and in both there were a small number of previously affected joints which became painless and a larger number of previously normal joints which became painful during the six-months course. Most of the affected joints, however, remained unchanged. The mean values in the two groups before and after treatment are shown in the table.

	Before Treatment			After 5 Months				
	Grip	E.S.R.	No. of Joints Affected	Grip	E.S.R.	No. of Joints		
						Recovered	Unchanged	Newly Affected
Control	215	22	22	180	26	1	21	4
Dienoestrol	210	23	19	200	26	1	18	3

FIG. 9.—Knee, showing marked "molten wax" osteophytes.

During the following six months the tablets were reversed, so that the patient previously receiving A now received B, and vice versa. The second six months has not quite been completed in all patients, but it is clear

that no change has taken place, except that while receiving B one or two patients noted uterine bleeding, and this, in fact, proved to be the active tablet. Although there were only 10 cases in each group the remarkable similarity in behaviour between the two groups suggests that dienoestrol in the dosage given fails to influence the arthritic process in any way.

In fact, we are not aware of any treatment which will influence the arthritic process, but many of these patients fear that they are suffering from rheumatoid arthritis and are grateful for an explanation of the nature of their complaint and its probable future course, and some relief may be obtained by the proper management of their arthritis. Thus acute painful episodes in the larger joints respond well to short periods of immobilization in plaster, and pain may also be temporarily relieved by local heat, which is most conveniently applied from an electric heating-pad that the patient can use in her own home. Aspirin analgesics may be helpful, but are not as effective in this condition as in rheumatoid arthritis. Surgical reconstruction of the larger joints is probably best avoided in these cases owing to the marked tendency for new joints to become affected. Fortunately most patients manage to continue a useful life, and it is only the exceptional case which becomes severely crippled.

Discussion

It would appear that the clinical syndrome which we have come to call primary generalized osteoarthritis has certain distinctive clinical and radiological features which enable it to be distinguished from secondary degenerative arthritis and also from rheumatoid arthritis and other allied polyarthritic conditions. Although generalized osteoarthritis has been recognized since the time of Heberden and Haygarth it appears to have been largely lost sight of in recent years, perhaps because it has been described under different names, such as nodosity of joints, menopausal arthritis, and so on. With the clearer definition of degenerative arthritis as an old-age change occurring prematurely in joints damaged by trauma, avascular necrosis, infection, or previous rheumatic disease, or in those worn out by occupational stress and faulty joint mechanics, a definite concept of osteoarthritis has developed.

The polyarticular form of osteoarthritis we have just described does not readily fit into this concept, and we suspect that this has led to its neglect and caused many cases to be classified as rheumatoid arthritis, or as atypical or "mixed" forms of arthritis. That rheumatoid arthritis may coexist with generalized osteoarthritis is very likely, as both diseases are common in middle-aged women, and in our series such a double diagnosis was made four times in 110 female cases. This, however, would be the expected number if the incidence were governed by chance, since in a recent field survey of the general population in a Lancashire town the incidence of rheumatoid arthritis was found to be 4% in the adult female population.

From the work of Stecher it would appear that idiopathic Heberden's nodes are exceedingly common in elderly people, and it seems likely that only in a minority of those affected are the symptoms severe enough to make the patient attend a clinic specializing in rheumatic disease, but in those who do attend such clinics multiple joint involvement is a common finding. We feel, however, that the question of the incidence of multiple joint involvement in people exhibiting asymptomatic

Heberden's nodes requires reinvestigation. In our series only 20 out of 120 patients gave a history of similar disease in their known relatives, but a very different incidence of Heberden's nodes might have been revealed if the relatives had been examined, and we have certainly seen families in which all the sisters were severely affected. We are therefore inclined to the view that generalized osteoarthritis as we see it in the clinic represents a severe form of Stecher's idiopathic nodes. If that is so, this syndrome, like the nodes, may result from an inherited defect, and should be regarded as a constitutional disease.

Although in the later stages the joint lesions resemble those of classical degenerative arthritis, we have been unable to find a description of the joint changes during the initial acute phase, and this point clearly requires urgent investigation, as the nature of the morbid process at this stage remains unknown. Our object so far has been to define what seems to be a distinct clinical entity, and thereby to stimulate further investigation into its pathogenesis and the aetiological factors which influence its development.

Summary

From a study of 391 cases of osteoarthritis attending a rheumatic clinic we have been able to define a distinct clinical entity for which we suggest the name of primary generalized osteoarthritis. This condition occurs most often in middle-aged women, and is characterized by a distinct pattern of joint involvement, by a course in which each affected joint passes through an initial painful and more or less acute arthritic phase, and by other distinctive clinical and radiological features.

Generalized osteoarthritis is a constitutional disorder affecting the diarthrodial joints and probably represents a severe form of idiopathic Heberden's nodes. A therapeutic trial of oestrogen therapy gave negative results, but patients suffering from this disease may be helped considerably by the proper management of their complaints.

The largest intake of first-year medical students for many years is reported by the Association of American Medical Colleges, who announced that 7,381 freshmen were admitted for the 1951-2 academic year (*New York Times*, January 12). It was also announced that applications for admittance had declined for the second year in succession. The fact that 30% of this year's applicants were applying for the second time is taken to indicate that about one of every two students who apply for admittance is ultimately accepted.

CORTISONE AND A.C.T.H. IN TREATMENT OF ANKYLOSING SPONDYLITIS

BY

F. DUDLEY HART, M.D., F.R.C.P.

*Assistant Physician and Physician-in-Charge, Rheumatism
Unit, Westminster Hospital*

In this country ankylosing spondylitis is still regarded by most workers as a separate entity from rheumatoid arthritis, and at the recent meeting of the European League against Rheumatism in Barcelona both Forestier *et al.* (1951), on clinical grounds, and Van Swaay (1951), on histological grounds, maintained that the two were different conditions. Most workers in the United States of America accept the two as one disease entity, and favour the term rheumatoid spondylitis. In the *Primer of Rheumatic Diseases* of the American Rheumatism Association the condition is given one paragraph of 27 lines, following Still's disease and Felty's syndrome, under the title "Variants of Rheumatoid Arthritis." Here it inevitably becomes lost, submerged in the general picture of rheumatoid arthritis.

Hart *et al.* (1949) have argued that until something is known of the aetiology of the rheumatic diseases there is little to be gained by merging two unknowns and stating that they are one, particularly when in the vast majority of cases the clinical, radiological, and therapeutic aspects are so very different in the two conditions. It may be that many more cases of diffuse spondylitis with peripheral involvement occur in the New than in the Old World; there may be a geographical difference in the manifestations of the rheumatoid diseases. Be that as it may, when treatment of rheumatoid arthritis is discussed in American papers one never knows how many cases are what we would call ankylosing spondylitis and how many are rheumatoid arthritis. For this reason the therapeutic results achieved by cortisone and A.C.T.H. in our first six cases of ankylosing spondylitis are here recorded.

Assessment of Improvement

Ankylosing spondylitis is in many ways a more difficult condition to assess objectively than rheumatoid arthritis, in which finger-swelling can be a convenient yardstick of therapy (Hart and Clark, 1951). Nevertheless in previous trials we have found patients with spondylitis much less suggestible than those with rheumatoid arthritis, and much less likely to respond dramatically to inert substances under the impression that they were receiving powerful therapeutic agents. We have used in assessment: (1) spinal flexion and extension, as measured by an angled "spondylometer," which, extending from sacrum to cervical vertebrae, eliminates hip movements; (2) simple forward bending which includes hip movement, measurement being taken from finger-tips to the floor at the tip of the big toes; (3) chest expansion, measured in inches at nipple level; (4) vital capacity estimations; and (5) subjective assessment of pain and stiffness by the patient himself, complete normality being taken as zero. Photographic contrast has not been sensitive enough to record small differences, and sedimentation rates have been so erratic as to be entirely unreliable. It will be seen, therefore, that, unlike the ring measurement of finger-swelling in rheumatoid arthritis, there is no absolutely objective measurement in ankylosing spondylitis which cannot be influenced by pain relief and psychological factors.

Case 1

A man aged 26 first had ankylosing spondylitis in 1945 in the lumbar region and the right hip. He was treated as a case of tuberculosis by immobilization in plaster for 10 weeks; but the pains became worse, and on removal of the plaster he was extremely stiff and required the aid of two sticks when walking. During the same period his general health deteriorated and he lost 28 lb. (12.7 kg.) in weight. In August, 1946, deep x-ray therapy was given to the right hip without improvement. Pain and stiffness became progressively worse, and in the winter of 1950-1 symptoms were intensified and the left hip became involved, with occasional pains and stiffness in the right shoulder. Extremely painful "muscle spasms" were a feature of the disease.

On admission to the unit in May, 1951, the spine was immobile throughout except for some movement at the atlanto-occipital and atlanto-axial joints. Hips were fixed in partial flexion. X-ray films showed poor intercostal expansion and fusion of sacro-iliac, hip, and lumbar and dorsal intervertebral joints. Although he was ankylosed and had a normal corrected sedimentation rate bouts of painful muscle spasm occurred in the back and thighs. Expecting little effect, we gave A.C.T.H. (Armour), 15 mg. six-hourly, intramuscularly, over a period of 17 days. No significant improvement in range of movement occurred and pain increased with this treatment, episodes of muscle spasm becoming more intense and frequent. Subsequently deep x-ray therapy was given—1,200 r to each hip and to the sacro-iliac joints. Muscle spasm disappeared for the first time and there was subjective improvement, pain lessening appreciably and well-being increasing.

Comment.—This case once again illustrates the dangers of wrong diagnosis and complete immobilization early in this condition. Although the case was an entirely unsuitable one, A.C.T.H. therapy was given, purely empirically. Attacks of painful muscle spasm, his most troublesome symptom, worsened on this treatment, but were relieved by subsequent deep x-ray therapy.

Case 2

A man aged 35 had suffered from ankylosing spondylitis since 1942. He gave the interesting history that when sleeping in an aeroplane on the Berlin air lift he woke up less stiff and with less pain than after sleeping in his normal bed. This history of ease by constant spinal agitation during sleeping hours has been noted also by J. Jackson Richmond (1950, personal communication) in a spondylitic patient sleeping in a small yacht at anchor. Symptomatic ease and measurable improvement followed deep x-ray therapy in August, 1948, and February, 1949, different areas being treated on the two occasions. Prior to readmission to the unit in November, 1950, there had been considerable pain in the sacro-iliac, subcostal, cervical, and right shoulder regions, with increasing stiffness and some anterior chest pain. For one year he had had intermittent mild dyspepsia.

Examination on admission revealed limitation of all spinal movement and scattered areas of bony tenderness. Painful haemorrhoids were present. X-ray films and tomography showed incomplete fusion of sacro-iliac joints and early longitudinal calcification between vertebrae, but the intervertebral joints were normal. A barium meal revealed a duodenal ulcer. A 10-day course of injections of an inert substance produced no change. A further 10-day course of a substance under trial also brought no improvement. Ten days of cortisone, given intramuscularly (total 1.3 g.), showed an increase of spinal flexion from 17 to 20 degrees, an increase of chest expansion from 1½ in. (4.4 cm.) at nipple level to 2½ in. (6.3 cm.), but a slight reduction in vital capacity and no reduction of a high blood sedimentation rate. Marked subjective improvement occurred, in that pain and stiffness were much less. No exacerbation of duodenal symptoms occurred.

The patient was unaware of the substances he was receiving, and his observations are therefore of interest. "On

January 2 [his 25th day of injection therapy and 5th day of cortisone] I could literally feel my condition improving hour by hour. I started taking a keen interest in food. Spondylitis, piles, and ulcer pains now suddenly became confined to their own particular sphere. Since then I have felt a great urge for exercise (not physiotherapy!), particularly badminton, and my general condition, both physical and mental, feels as though it has been brought about by a process of rejuvenation rather than by a cure. Since January 2 I have not slept well, and the last three nights have been very wakeful ones, though my mind has been very tranquil. I have not slept in the day-time as usual, as I haven't felt tired enough." Unfortunately injections ceased four days after; so did entries in his diary and all subjective improvement. After discharge in May he was given deep x-ray therapy to the dorsal and cervical spine (900 r) as an out-patient, and subjective improvement, though less rapid and dramatic than on cortisone, was much more lasting: the follow-up note on October 17, 1951, read, "Has held improvement gained as a result of radiotherapy."

Comment.—Cortisone gave marked subjective improvement, but little could be demonstrated by measurement, and the improvement rapidly disappeared after treatment ceased. Deep x-ray therapy, to painful areas only, produced a less dramatic though much more prolonged effect, improvement being still maintained five months later.

Case 3

A man aged 20 had a four-year history of ankylosing spondylitis. All spinal movement except cervical was restricted; tender areas were present in the left anterior superior iliac spine, left greater trochanter, left lower ribs postero-laterally, and right adductor tubercle. X-ray films showed marked involvement of sacro-iliac joints and of both ischial tuberosities. There was slight "squaring" of the bodies of the lumbar spine, and many of the intervertebral articulations were affected. The ribs moved normally on inspiration. Vital capacity was 3,400 c.cm., or 85% of normal. A 10-day course of intramuscular cortisone was given (total 1.3 g.), and subsequently a course of deep x-ray therapy, 1,200 r, to the sacro-iliac, lumbar, and thoracic ports. Results are as noted in Table I.

TABLE I.—Results in Case 3

	Cortisone*		7 Days Later	After Deep X-ray Therapy
	Before	After		
Pain	100	30	100	50
Stiffness ..	150	30	100	50
Forward flexion ..	18 in. (45.7 cm.)	13 in. (33 cm.)	16½ in. (42 cm.)	14 in. (35.6 cm.)
Spondylometry ..	24°	32°	21°	33°
Chest expansion ..	3½ in. (8.8 cm.)	4 in. (10 cm.)	2 in. (5 cm.)	4 in. (10 cm.)
Vital capacity ..	3,400 c.cm. =85%	3,620 c.cm. =91%	3,320 c.cm. =83%	3,800 c.cm. =96%

* 1.3 g. given intramuscularly over 10 days.

Comment.—It will be seen that assessments of improvement by the medical attendant and the patient were approximately equal on cortisone and deep x-ray therapy, but, while the effect of the former wore off within five days of stopping treatment, the increase in spinal flexion has been maintained since x-ray therapy, the figures being 43 degrees two months after therapy and 32 degrees seven months after. Improvement at this time was still maintained, pain and stiffness being much less than before treatment.

Case 4

A male aged 41 had suffered from ankylosing spondylitis for less than one year. Morning stiffness and pain were present in the right foot as well as the sacro-iliac and cervical areas. Spinal flexion was reduced to 37 degrees and extension to 5 degrees (total range 42 degrees), chest

expansion was 1½ in. (4.4 cm.) at nipple level and vital capacity 3,480 c.cm. (73% of normal). X-ray films and tomographs showed early changes of ankylosing spondylitis in both sacro-iliac joints; no other changes were present in the spinal column. Osteoporosis of both feet was present, with some erosion of the heads of several metatarsals on the right side. The patient was an excellent witness, and kept a careful record of his impressions day by day. Looking through these, it is apparent that on all forms of treatment, including administration of inert substances, a steady all-round improvement took place (Table II), except in the

TABLE II.—Results in Case 4

	Before Treatment	After A.C.T.H.*	After Deep X-ray Therapy
Pain	236	155	101
Stiffness ..	236	121	77
Forward flexion ..	5½ in. (14 cm.)	4 in. (10 cm.)	0 in. (touching floor)
Spondylometry ..	51°	47°	60°
Chest expansion ..	1½ in. (4.4 cm.)	2 in. (5 cm.)	2 in. (5 cm.)
Vital capacity ..	3,480 c.cm. =73%	3,600 c.cm. =76%	3,700 c.cm. =78%

* 645 mg. given over 14 days six-hourly.

right foot, which remained painful and stiff throughout a 12-day course of A.C.T.H., 70 mg. being given on the first day in six-hourly dosage, followed by 10 mg. six-hourly for a further 11 days, and a course of deep x-ray therapy applied to the spine. Only when a small (500 r) dosage of deep x rays was given direct to the foot did improvement occur locally.

Comment.—A.C.T.H. in small dosage had no dramatic effect on spinal symptoms: steady improvement took place throughout his stay, irrespective of the form of treatment given. Pain, stiffness, and tenderness in the right metatarso-phalangeal area remained an annoying drawback to progress when spinal symptoms had largely abated. A.C.T.H. and spinal deep x-ray therapy had no effect; local deep x-ray therapy in small dosage produced an immediate response, which has been maintained to date (five months later).

Case 5

A man aged 23 with a history, starting in 1947, of swelling of the left knee and stiffness of the lumbar spine, was diagnosed in 1948 as a case of ankylosing spondylitis and was put into a plaster jacket. In this he became more stiff and the disease progressed and extended, the hips becoming involved. He was removed from the jacket and was given exercises and deep x-ray therapy.

On admission in March, 1951, his spine had a range of 34 degrees. Movements of both hips were restricted, but

TABLE III.—Results in Case 5

	A.C.T.H.*		3 Days Later	After Deep X-ray Therapy
	Before	After		
Pain	70	85	85	80
Stiffness ..	85	80	90	75
Forward flexion ..	10½ in. (26.6 cm.)	10½ in. (26.6 cm.)	10½ in. (26.6 cm.)	10 in. (25.4 cm.)
Spondylometry ..	38°	43°	40°	40°
Chest expansion ..	1½ in. (4.4 cm.)	1½ in. (3.8 cm.)	1½ in. (4.4 cm.)	1½ in. (3.2 cm.)
Abduction malleoli	38 in. (96.5 cm.)	41 in. (104 cm.)	38 in. (96.5 cm.)	39 in. (99 cm.)

* 625 mg. given over 15 days six-hourly.

less so than when first seen in 1948. The left knee was slightly swollen, and tender areas were present in the lower ribs, coccyx, and sacrum. X-ray films showed ankylosis of sacro-iliac joints and most of the lumbar intervertebral joints. The patient was given routine exercises and allowed full mobility. Control injections were given for 13 days, followed by a 15-day course of A.C.T.H., 10 mg. six-hourly

intramuscularly. Subsequently deep x-ray therapy was given—900 r to the sacro-iliac region, 1,000 r to the right hip. He was discharged four days after x-ray therapy was finished, measurements immediately before and after each form of therapy being unchanged (Table III) and no subjective improvement having been noted. No diminution in knee-swelling and no reduction in bone tenderness occurred.

Comment.—No improvement whatsoever was noticed with either control or A.C.T.H. injections, and there was no immediate response to deep x-ray therapy.

Case 6

A woman aged 40 had developed acute diffuse back pains suddenly in January, 1951, with fever and general malaise. By the middle of the afternoon she had to retire to bed. Next day her back "felt like a ramrod" and severe spasmodic pain was present. Two days later her knees became swollen. Salicylates had no effect. She then remembered she had had two similar bouts at the age of 19 and 23 years, both being characterized by severe pain and stiffness of the back and swelling of the knees, as in her present bout. Since these two attacks she had been perfectly well, though her back became very painful if traumatized only slightly.

On admission on January 17, 1951, fever was present. She looked ill and was in great pain. Her spinal movements were restricted, her chest expansion markedly so. Both knees were swollen with fluid and were stiff and painful. Double-exposure x-ray films showed very limited rib movement with large diaphragmatic excursions. The sacro-iliac joints were eroded, with marginal ilial sclerosis, the picture being that of ankylosing spondylitis. Diarrhoea was present, but no pathogens could be isolated. Blood cultures and agglutinations were negative. Vital capacity was reduced to 50% of normal. Legs were splinted, and after a week's observation period, during which temperature and pulse failed to abate and the general picture remained unchanged, A.C.T.H., 15 mg. six-hourly, was started. On the first day fever abated, and within 48 hours pains and stiffness diminished, the legs appeared less swollen, and appetite and general well-being were much improved. Treatment was continued for a month, the dosage gradually being reduced; in the last two days she received only 16 mg. a day (4 mg. six-hourly). There was no rebound when therapy was discontinued. After eight days, when the dosage of A.C.T.H. was reduced to 32 mg. daily, a low fever and tachycardia returned for a time. Three days before A.C.T.H. was discontinued vital capacity had risen to 65% of normal. At her last out-patient attendance in September, although vital capacity was 68% of normal, x-ray films showed rib movement restricted as before. Overall improvement had been maintained, swelling of knees had disappeared, and she was working in a school.

Comment.—This acute episode in a female patient with spondylitis responded satisfactorily to A.C.T.H.; there was no rebound after gradual withdrawal of the drug, and in an eight months' follow-up improvement has been maintained. Therapeutic response has apparently run into natural remission.

Comment

It is fair comment that at least one of these patients could not be expected to give good results with A.C.T.H. or cortisone therapy, and that the more early acute cases did benefit, although dosage in all cases was low and periods of administration were short. In Case 6 improvement rapidly initiated by A.C.T.H. has been maintained and a natural remission appears to have set in with the discontinuance of treatment. In this patient, the only female of the series, two less acute episodes many years previously had subsided similarly, leaving her symptom-free for years. The effects of A.C.T.H. or cortisone on these six cases may be stated thus:

Case 1 (advanced case).—Pains worsened on therapy, painful spasms becoming worse. Deep x-ray therapy subsequently lessened pain.

Case 2.—No measurable improvement. Symptoms were relieved by cortisone, and also, less dramatically but over a much longer period, by deep x-ray therapy.

Case 3.—Measurable and symptomatic improvement occurred equally with both cortisone and deep x-ray therapy, the former lasting only for the duration of treatment, the latter many months subsequently.

Case 4.—Gradual improvement occurred on all forms of treatment, including the administration of inert substances. Cortisone failed to affect peripheral pain and stiffness, which responded to a small dose of locally applied deep x-ray treatment.

Case 5.—There was no immediate measurable or symptomatic response either to cortisone or to deep x-ray therapy.

Case 6.—Improvement occurred rapidly on A.C.T.H., natural remission setting in early.

It seems reasonable, with supplies of these drugs limited as they now are, to restrict their use to acute painful episodes in cases of spondylitis. Such episodes may be prostrating at the time, and few things cause more severe diffuse pain. Deep x-ray therapy has in our hands proved most effective within seven to ten days of starting treatment in such cases in the past, but A.C.T.H. or oral cortisone obviously can play a part here in controlling acute symptoms and so enabling other forms of therapy to be instituted.

Ankylosing spondylitis is a disease which lasts for many years or the rest of the patient's lifetime; one is never sure that even a prolonged remission of many years will be a permanent one. Most patients are only moderately incapacitated, and the vast majority are at work and earning their living. A.C.T.H. or cortisone therapy can be applied only over a relatively short period in the life history of the disease. Case 6 seems eminently suitable for two reasons: (1) the acute prostrating episode demanded immediate pain-relieving, effective treatment, and (2), the patient being a female of child-bearing age, deep x-ray therapy held certain hazards.

Even if supplies of A.C.T.H. and cortisone were completely unrestricted it is very arguable if they would be more than short-term weapons in the treatment of ankylosing spondylitis, for they are in no sense curative. In spondylitis stiffness is a prominent symptom, and in all but early cases this is, in part at least, due to irreversible change. Bony tenderness in our cases has not, on the short courses of treatment given, been relieved by A.C.T.H. or cortisone as it has been by deep x-ray therapy. Exercises, postural drill, and treatment of postural defects remain as necessary as before. The basic treatment of this condition remains unchanged, though a potent short-term weapon is now available for more acute episodes.

Summary

Six cases of ankylosing spondylitis treated with short courses of A.C.T.H. and cortisone are described. Reasons are given for regarding the present current therapy as unchanged in this disease, although a potent weapon for short-term treatment of acute painful episodes has been placed in our hands.

A PSYCHIATRIC STUDY OF SIX CASES OF INFANTILE ACRODYNIA

BY

DUNCAN LEYS, M.D., F.R.C.P.

Senior Physician, Paediatric Unit, Farnborough Hospital,
Kent

AND

KENNETH CAMERON, M.B., F.R.C.P.Ed., D.Psych.

Consulting Physician, Maudsley Hospital and Bethlem
Royal Hospital

In a review of infantile acrodynia, one of us (Ley, 1950) commented on the similarity between acrodynia and the clinical picture described by Spitz and Wolf (1946) in children deprived of their mothers. Without insisting on an absolute parallel, he suggested that there were grounds for investigating the emotional state of cases suffering from acrodynia. While to the perceptive and experienced eye the clinical picture presented by emotionally disturbed infants shows many variations, these must be subjectively interpreted and are open to dispute. It is a truism of paediatric or child psychiatric practice, however, that the emotional state of the mother profoundly influences the emotional state of the child. This was described thirty years ago by Hector Cameron (1919) and has been the subject of many studies and observations. Thus Levy (1943) states: "It is generally accepted that the most potent of all influences on social behaviour is derived from the primary social experience with the mother. . . . His outlook on life, his attitude towards people, his entire psychic well-being, his very destiny is presumed to be altered by the maternal attitude." For the purpose of this report it is unnecessary to enter into discussions on how maternal attitudes influence the emotional state of the child. It is, however, well within the observation of child psychiatry that a child may experience the result of emotional stresses that the mother herself fails to recognize.

In view of these considerations it was arranged that, in each case of acrodynia met with, the family background of the child's life should be investigated, as is done with psychiatric problems. This in practice resolved itself into the psychiatrist interviewing the mother, or both parents, while the paediatrician treated the child. In two of the cases the parents themselves referred other children of the family who suffered from psychiatric disability, so that our knowledge of the family situation was much increased.

Treatment and prognosis are not discussed here; the symptoms and signs of acrodynia cleared up in every case.

Case 1

A girl, admitted at 15 months, had been a model baby. At 8 months she had suffered from constipation and a prolapsed rectum. For two months before admission she had had "teething rashes," treated apparently by exclusion of cream, butter, cod-liver oil, and vitamin preparations from her diet. When seen at 15 months the child was described as listless, off her food, sleeping badly, whimpering, and wanting to be lifted. She sweated a lot, and her hands in the past two weeks had become pink. On examination she was pale, had obviously lost weight, resented being touched, and tended to kneel with her face buried in the pillow (photophobia). She was otherwise apathetic, with hypotonic limbs. Tachycardia (175) and raised B.P. (174/120) were present. Her hands and feet were red and cold. The

liver was enlarged below the costal margin. There was some sweat rash over the rest of the body.

The mother, a pleasant young woman, had been a clerk before marriage and sang in the church choir. Her mother was a worrier and was strict in her religion; her father was healthy and easygoing. The patient's father, aged 23, also a clerk, was quiet but with a temper. His mother was much concerned with what people think; his father was easygoing. The parents were engaged when the child was conceived, and both grandmothers were greatly exercised over the scandal in two respectable families. The marriage was hastened on, and the couple were found rooms in the house of the paternal great-grandmother. Here they found conditions impossible; they were limited in coal, and were not allowed to make any noise at night or before 10 in the morning. The mother was forbidden to do washing in the rooms, as it would make the walls damp. She said that caring for the child in these conditions got her nerves "in a state." She felt upset and fed up; nothing was right, and she was inclined to snap at everyone. She attended the doctor for her nerves. It was in this situation that the child's symptoms developed.

When interviewed the mother seemed a pleasant, competent young woman; the circumstances of her marriage were still a preoccupation, and after "confessing" them she spoke of her concern that the child would one day find out.

Comment.—In this case the child was conceived against the wish of the parents and precipitated the marriage. Its presence was associated with much self-reproach to the mother. In addition it had created great maternal difficulties for her, and she had reacted to these stresses with nervous symptoms at the time of the illness.

Case 2

This child was admitted to hospital at 22 months. Birth had been normal; she was breast-fed for two weeks and was put on the bottle when her mother got up. Physical development had been normal up to the onset of the illness, but the child had rocked her cot and when ill she had banged her head. She still picked her woollens and ate them at the time of admission. The normal physical progress had been interrupted two months before admission. The child was fretful and cried when cutting teeth, and did not improve when the teeth came through. She stopped talking, was whining and fretful, slept badly, had loss of appetite, and sweated; her hands were red, hot, and moist, and her feet cold; she tended to constipation and showed doubtful photophobia. Her mother described her as "limp." At the time of admission there had been some improvement, but the child was whining and miserable, was unwilling to sit up, had acrocyanosis of hands and feet, showed tachycardia (140+), and had raised B.P. (145/95). Tuberculosis, of which there was a history on the paternal side, was excluded. The diagnosis of acrodynia was made.

A family background of stress was revealed. The mother, aged 36, grew up in an unhappy home with shortage of money. The maternal grandfather suffered from bronchitis. The maternal grandmother went out to work. The mother as a girl had resented having to work in the house. When she was 17 the maternal grandmother was killed in an air raid and she thereafter kept house for the maternal grandfather and a maternal uncle. She found herself ignorant domestically and was filled with self-reproach at her previous attitude to her mother. She married at 20. The father, a bus conductor, at the time of the child's admission aged 36, was a heavy, anxious, down-in-the-mouth individual, a non-smoker and non-drinker.

The eldest child, aged 6, showed some personality disturbance referable to parental anxiety and mishandling. He was timid, withdrawn, a "bundle of nerves" would not go out, had attacks of vomiting, became agitated on separation from the parents. He was brought for treatment. The second child, aged 3, had been in hospital suffering from strangulated hernia. The patient, the third child,

had been unwanted, and represented a failure in birth control. The mother described herself as tired and "so depressed I can hardly breathe" since she knew she was going to have this child. She had sickness all through this pregnancy, though not with the other children. Since this child had gone into hospital she had suffered from headaches. In view of the failure of contraception, with the consent of the father, and supposedly on the advice of the family doctor, sexual intercourse between the parents had ceased with the birth of this child. The home was good from the point of view of space and activity.

The mother was a pleasant drawn-looking woman, tired, and attending the family doctor for "nerves," but formally good with the children, manifesting no lack of affection.

Comment.—The factors of stress appear to be in the mother's history, in the determination and failure to limit the children to two, and in the disturbed marital situation. The severely disturbed eldest child and the patient's rocking, head-banging, and picking suggest lack of maternal warmth and over-restriction. The patient was confessedly an unwanted child, and the mother had shown psychosomatic symptoms from the time of conception.

Case 3

This patient was admitted to hospital aged 9 months. The history was of a normal pregnancy and birth. She was breast-fed for four to five months and weaned from the breast without difficulty. Previously healthy, the child about two months before admission lost interest, cried a good deal, became limp, slept badly, lost appetite, and lost 2 lb. (0.9 kg.) in weight. A month before admission her hands and feet had become swollen and cold. A week earlier a rash had developed on the body and the child had a blister on one toe. On examination she was irritable and tearful, with a flushed facies. Hands and feet were red, cold, and sweating, there was a papular rash on the trunk, and some of the skin creases were broken. Moderate tachycardia was present (160), and the blood pressure was 140/100. Hypotonia was marked, and the child was found to be running a slight evening temperature. Infantile acrodynia was diagnosed.

The mother, aged 21, a shorthand-typist, had married at 19. The maternal grandmother was highly strung, and the grandfather had been disabled in the first world war. The father, aged 30, was an electrician of healthy parentage. The marriage had been happy, but circumstances were difficult. They had two rooms, but the children arrived too quickly; the eldest was 2 months old when the patient was conceived, despite attempted birth control. "I did not want her." The landlord, wife, and two children also lived in the house. "They don't want children crying all night." They kept bees outside her window, which frightened her, and she continually dashed out to take the child in when they were disturbed. The dog frightened her and the children. The mother had felt overwrought since the birth of the patient, who had cried at nights; the mother had been both irritable and self-reproachful. She had difficulties with the landlady, and was unable to keep the place straight or work a shared kitchen. Sexual relations had been unsatisfying to her. She was inclined to blame the husband for this, but her own fear of conception had probably been the main factor. In the month before the child's illness began the mother said she had become hysterical and had attacks of screaming and weeping, for which she attended her doctor. Seen with the child, she held her with kindness and care.

Comment.—This child was also conceived contrary to the parents' wish. The material difficulties for the mother were great and were aggravated by the child's birth. The child's illness had developed when the mother was attending her doctor for acute nervous symptoms.

Case 4

This child, a girl aged 14 months, had been born at home and had been breast-fed for five months. Her maximum weight was 24 lb. (10.9 kg.) at 12 months. At the time of examination it was 19 lb. 10 oz. (8.8 kg.). She was said to be "feverish" when cutting each tooth. Four weeks before examination she had begun to cut her canines. She had been off her food, had vomited, was restless at night as with her other teeth, but now showed complete refusal of food, and became very passive, although restless and making chewing movements. She refused to be bathed or dressed. On examination she lay quiet in her parent's arms and resented interference. There was gross subcutaneous wasting, mainly over the abdomen, but also in the limbs, which were hypotonic. There was no hypersensitivity or photophobia at the time, but later some evidence of hyperaesthesia. Her heart rate was 160. The systolic pressure (narrow band) was >140. She could stand and walk. Infantile acrodynia was diagnosed.

The family situation and the mother's health were much disturbed. She had been restricted by her own mother, who had disliked her, and she was attached to her father. At 20 she had had a breakdown with attacks of screaming while in the W.A.A.F., after she had picked up a dead baby in an air raid. The father, a student, came of excitable parents. An elder child was born in 1943. The patient had been born when the husband went back to student life after the war. They occupied a small flat and had an "awful" landlady. The husband was studying, and the children had to be kept quiet in the evening, while the baby shared their room. During this time the older child attended a child guidance clinic for pilfering and restlessness, and the mother attended a psychiatrist for anxiety symptoms, phobias, and hysterical manifestations. They had just moved out of this situation when the child's illness began. Subsequently both the elder child and the mother received treatment again.

Comment.—The mother's bitterness against the grandmother was increasingly revealed as creating difficulties for her in a maternal role. This was regarded as the essential element in her problems with her children, though the factor of restriction and crowding did come in. While the mother accused herself of irritability with the children, particularly the eldest, she handled the patient with apparent affection.

Case 5

A girl just over 12 months old was admitted to hospital with a history of a normal maternal first pregnancy and healthy delivery. She had always been a light sleeper. She was breast-fed for only three weeks and then put on the bottle, making a steady gain up till about two months before admission.

At this time she began to refuse feeds and was disinclined to sleep. She would lie and whimper, although yawning all the time. She would play if taken into the parents' bed and eventually slept. When transferred to the care of the maternal grandmother for a few days she tended to improve. At 9 months she could stand and crawl, but had made no progress since and lay passive. She now liked to be cuddled, although initially had shown little response to it. In two months she had lost 2 lb. (0.9 kg.) in weight. She sweated a lot in sleep.

On admission she resented being handled, and her appetite and sleep were poor. There was hypotonia, with some acrocyanosis of hands and feet. The heart rate was 120–130, and B.P. 110/60. Her temperature was normal, as were her gums and mouth. X-ray films of the chest were negative, the Mantoux test was negative, and the blood picture and white cell count were normal. She was considered to be a mild or doubtful case of acrodynia.

The background of stress in the child's life was acute. The mother, aged 28, had a stable family background. The

father, aged 35, was a cheerful individual. The paternal grandmother was, however, a dominating woman, and her husband had to conform. The child's parents had been married for two years. They lived in two rooms in the house of the paternal grandparents. Friction had quickly developed between the mother and her mother-in-law, and was aggravated after the birth of the patient. The two women had ceased to speak to each other. One of the rankling accusations made by the grandmother was that the mother did not love her child. Relations between the parents were also strained because the mother had refused sexual intercourse since the birth of the child, as she refused to take the risk of another pregnancy in these circumstances. Both refused to undertake birth control. She felt also that it was the duty of the father to provide her with an adequate home, and her determination had a punitive element in it.

The mother felt that her initial easy disposition had gone and that she was becoming spiteful, irritable, and cross with the child. It was in this situation that the symptoms complained of developed.

The mother was, on interview, a pleasant woman and did not show formal mishandling of the child.

Comment.—The factors present appear to be acute maternal stress related to the housing position, her mother-in-law, and her marital relations. This was so marked as to cause her to report a change in her personality. The grandmother's accusations that she did not love her child may be important.

Case 6

A boy aged 13 months was admitted to hospital. Pregnancy and labour were reported to have been normal except that the mother had oedema in the latter months. He was breast-fed, and was not weaned until 11 months. At 9 months he had had mild whooping-cough. At this time he had weighed 16½ lb. (7.5 kg.); his weight of 18 lb. (8.2 kg.) on admission almost certainly represented a loss of weight. About a month before admission he had begun to refuse feeds, became cross and restless, showed dislike of the light, and developed a fine rash on the body. On examination this was found to be a characteristic but not very severe case of acrodynia, with photophobia, tachycardia, swelling of the hands, hypotonia, moodiness, difficulties with feeding, and a tendency to sweat. On admission he was noted to be rather dirty and uncared for.

The mother, aged 41, a stout, apparently genial, slightly slatternly-looking woman, said she was "always tired"; she also said she was sometimes depressed, but made light of this. She herself had been adopted after the death of her father, and spoke of the maternal grandmother with detachment and of the adoptive parents with affection. The father, aged 41, suffered from duodenal ulcer, and was irritable and moody. There was nothing significant in the paternal grandparents.

The patient was the seventh child, and five older ones were still at home. The father had to work overtime to keep going financially, and gave the mother £5, in addition to which she had an allowance of 25s. weekly. The home was a house with six rooms and a kitchenette and bathroom. The mother indicated that she used to take a pride in keeping the house nice, but no longer did so, and confirmed that she had not wanted the child, and, indeed, half-hearted birth control had been practised since the third child; she did, however, say that it was all right when they were there.

Comment.—Here the factors of the child's being initially unwanted and some degree of stress were both present. The mother herself suffered from continual tiredness and was occasionally depressed. It may be said that the findings in this case were compatible with rather than strikingly illustrative of the elements found in the other cases in the series.

Observations

The evidence of stress in the family situation of these cases is striking, and indeed more obvious than that in the family of many children attending the psychiatric clinic.

In Cases 1, 2, 3, and 4 the mothers were actually attending the family doctor or a psychiatrist for nervous symptoms when the child developed the symptoms. In Cases 5 and 6 the mothers respectively complained of irritability and spitefulness and of tiredness and depression.

In a consecutive series of 30 cases of manifest psychiatric symptomatology referred by the paediatrician to the psychiatrist in the same clinic, maternal symptomatology of this kind was present in only eight cases (Prince, 1951).

In Cases 1, 2, 3, and 6 the children were the result of failure of contraceptive methods and their conception was unwanted. It may be important that in Case 5 the paternal grandmother accused the mother of not loving the child. In Case 4 the mother, who subsequently received psychotherapy, revealed severe emotional difficulties in relation to her children. All these mothers, with the possible exception of Case 6, were, however, formally good mothers who showed care for the welfare of their children. Nevertheless, it is a familiar experience in child psychiatry to meet mothers who, though overtly affectionate, cannot show complete maternal warmth to their infants. The other element present with surprising consistency was the need to restrict the child's crying or activity. This was demonstrably present in Cases 1, 3, 4, and 5, while in Case 2 the child's rocking, head-banging, and picking are signs usually associated in the mind of the psychiatrist with lack of maternal warmth and over-restriction.

In these cases, therefore, we would say that the essential element present was some degree of emotional deprivation associated with the child's being unwanted, and with other maternal stresses and some evidence of over-restriction. This occurred in families reasonably well disposed towards the children. No effort has been made to present more than the manifest situation, and psychodynamics are not discussed.

The series is small, so that an element of coincidence cannot be excluded, but it does contain all cases of acrodynia which attended a paediatric clinic at the time, and there was no selection of cases on any basis other than the symptoms of acrodynia.

In our view the evidence is sufficient to warrant extended observations of the emotional and family background of infants suffering from acrodynia.

Summary

Six cases of infantile acrodynia are described in their family setting and environment. In each case evidence is offered that the child suffered from emotional deprivation, and that the mother was herself suffering from psychiatric ill-health at the time of onset of the child's illness. The circumstances were conducive to restriction of the child.

AMINO-ACIDURIA IN GALACTOSAEMIA

BY

A. HOLZEL, M.D., D.C.H.

G. M. KOMROWER, M.B., Ch.B., M.R.C.P.

AND

V. K. WILSON, M.Sc.

(From the Department of Child Health, University of Manchester)

During recent years the condition of galactosaemia has been recognized more frequently, but the total number of cases recorded in paediatric literature is still very small. Much interest has been aroused by this rare metabolic disorder because of the satisfactory results following appropriate treatment and because of the serious consequences of misinterpreting the clinical picture. Although diagnosis and treatment are now on a firm basis, the pathogenesis and the nature of the metabolic derangement are not yet fully understood.

Two Recent Cases

During the past four months two infants have been observed who presented the classical symptoms and signs of vomiting, failure to thrive, transient jaundice, enlargement of the liver, and frequent loose stools. One,

who has been studied from the first days of life, developed central polar cataracts at the age of 4 weeks; these have subsequently regressed. Examination of the urine in each case showed the presence of a reducing substance which was identified both chemically and by chromatography as galactose. The galactose-tolerance tests in both infants were grossly abnormal, showing an initial galactosaemia, a steep rise of the galactose blood levels, and a slow fall over several hours.

Further evidence supporting the diagnosis was obtained by the therapeutic test of omitting milk from the diet; this produced definite improvement in the infants' condition and led to the disappearance of galactose from the urine.

Because of the hepatomegaly in the first infant the possibility of an amino-aciduria as a result of liver damage was considered and studies of the urine were undertaken. Because of the unusual findings these studies were repeated with the second infant.

Urine Chromatography

One-way paper chromatograms were made on as many specimens of urine as possible, the volume of urine containing 250 μ g. of total nitrogen being taken for each analysis. Both cases consistently showed an excessive amino-aciduria when on a milk diet but not when on a diet from which milk was entirely absent. The picture reappeared when 2 g. of galactose a day was added to the milk-free feeds. It also followed a galactose-tolerance test.

In order to identify the amino-acids more definitely two-way chromatograms were made on urines selected on the basis of the one-way chromatography, using phenol/collidine and phenol/tetrahydro furfural alcohol as pairs of solvents and again taking the volume of urine containing 250 μ g. of nitrogen. These chromatograms confirmed the previous findings and allowed of a provisional identification of all the amino-acids present. The details of the amino-acid pattern were similar in both cases. Descriptive diagrams of two chromatograms of the urine in each case are shown in Figs. 1, 2, 3, and 4. The amino-acid spots are shown in their usual positions on an actual chromatogram. They are drawn in the form of circles, the relative sizes of the circles giving some indication of the strength of ninhydrin colour and hence of the quantity of each amino-acid present. The urine is assumed to have been placed at the right-hand bottom corner. Phenol has been run as first solvent from right to left followed by collidine in an upward direction.

It can be seen that on the milk diets a definite amino-aciduria was present, involving a large number of amino-acids. A two-way chromatogram of the first case after the administration of galactose showed practically the same pattern as the original urine. It was noted that the pattern obtained was different from any pattern seen in cases of extensive liver damage in infants of the same age.

Chromatographic Report

It was felt that confirmation of the amino-acid pattern should be obtained, and Dr. Dent, of University College Hospital, kindly examined specimens. He reported as follows: "Review

FIG. 1.—Urine of Case 1 while on a milk diet. Note the large number of amino-acids, some of them in large quantities.

FIG. 2.—Urine of Case 1. After four days on a milk-free diet. All the amino-acids have decreased in quantity—some have disappeared altogether. The excretion is still, however, slightly abnormal.

FIG. 3.—Urine of Case 2 while still on a milk-containing diet. The characteristics of the amino-aciduria are very similar to those shown by Case 1.

FIG. 4.—Urine of Case 2 on a milk-free diet.

Identification of Spots.—1, Cysteic acid (from cystine); 2, aspartic acid; 3, glutamic acid; 4, serine; 5, glycine; 6, threonine; 7, alanine; 8, glutamine; 9, tyrosine; 10, phenylalanine; 11, leucine; 12, valine; 13, alpha-amino-n-butyric acid; 14, methionine sulphone (from methionine); 15, histidine; 16, citrulline; 17, beta-amino-iso-butyric acid; 18, methyl histidine; 19, arginine; 20, lysine.

of all the chromatograms leaves no question that there is a gross amino-aciduria associated with the galactosuria, which rapidly becomes more normal under treatment with the milk-free diet. The especially unusual characteristics (as against those of the already known amino-acidurias) are the disproportionately large quantities of serine, threonine, methyl histidine, lysine, and tyrosine. It could be that this pattern is specific for the disease. Of especial interest is the fact that the common liver diseases, so far as they have been investigated, display urine amino-acid patterns quite different from those shown by these two cases (Dent and Walshe, 1951). On the other hand, the pattern shows some resemblance to that occurring in the renal amino-acidurias, especially that of Wilson's disease."

Discussion

Pathological excretion of amino-acids in urine has recently been reviewed by Dent (1950, 1951), and it appears that there are two possible mechanisms by which this may occur. The first is the "overflow" mechanism whereby the excretion is the result of a raised plasma level; this occurs to varying extents in both acute and chronic liver disease and in phenylketonuria. The second is a true "renal" mechanism whereby the excretion occurs in the presence of normal plasma levels, presumably as the result of a lowered kidney threshold—that is, raised clearance; this occurs in cystinuria, in the Fanconi syndrome, and in Wilson's disease, all of which have a genetic background. There is also an acquired form of renal amino-aciduria which occurs occasionally as the result of the action of poisons such as lead and uranium on the renal tubules.

No reports have as yet appeared in which a disorder of amino-acid metabolism has been implicated in galactosaemia, but it is possible that this amino-aciduria may be specific and an expression of a "renal" mechanism.

It is hoped to publish the results of further work on these lines in the near future.

We are grateful to Dr. C. E. Dent and his assistant, Miss Dorothy Fowler (University College Hospital Medical School), for their generous help with the sugar and amino-acid chromatography and its interpretation; to Miss Jean Summerscales for her assistance in the chemical identification of the galactose; and to Professor Wilfrid Gaisford for his interest and criticisms.

The Central Council for the Care of Cripples recently produced a *Summary of Legislation and Directory of Organizations for the Care of the Physically Handicapped* (Heinemann Medical Books, price 5s. 6d.), which, in spite of its unwieldy title, is a useful little book of over 100 pages which should be close to the hand of everyone, medical or lay, concerned in the treatment and care of the disabled or crippled. The addresses and functions of many local voluntary societies are included, as well as clear summaries of the provisions of the National Assistance and National Health Service Acts, and other forms of Government aid. There is also a section on the training of orthopaedic nurses and welfare workers as well as of the handicapped themselves.

EXTENSIVE RESECTION OF THE SMALL INTESTINE

A. SHORT REVIEW, WITH TWO NEW CASES

BY

H. J. CROOT, F.R.C.S.

Lecturer in Surgery, University of Bristol; Surgeon, United Bristol Hospitals

Resection of a large part of the small intestine is called for infrequently and usually unexpectedly. The occasion may be an emergency operation for adhesion obstruction, strangulated hernia, mesenteric vascular occlusion, or mesenteric injury. Less often the indication is widespread tuberculous or other disease of the small intestine, while occasionally it is malignant disease or a benign tumour involving the mesentery. In any case, the need for so drastic an operation has seldom been foreseen and a decision has to be made on the spot. Textbooks on operative surgery give little information, and although many articles on this subject have been published it is still not easy to find out what risk there is of serious impairment of health after an extensive resection. The satisfactory results in the two cases here reported and a review of some of the literature have considerably increased my optimism with regard to this operation.

Extent of Removal

It is true that in most cases the amount of bowel removed is decided by the disease rather than by the surgeon, but even in these there is sometimes room for judgment in deciding whether an extra foot or two of bowel is better removed or left behind. In a minority of cases the extent of removal is far more a matter for individual opinion. The surgeon's decision on how far he should jeopardize the patient's future health by increasing the scope of the operation must be based on his knowledge of the likely effects of removing a large part of the small bowel. If they were to be almost inevitable chronic invalidism, diarrhoea, and misery, then he would serve his patient best by conserving as much as possible. If he knew that several feet more or less would make little difference as regards future health, he would plan the operation accordingly, for long resections are no more difficult or dangerous than short ones.

The case records surveyed support the view that resections of up to one-half of the small intestine are not followed by serious metabolic disturbance. When they exceed three-quarters, then serious metabolic disturbance is probable but by no means certain. There is no clear indication whether resection from the proximal or the distal end is likely to have the greater effect. In practice most massive resections are distal, and the bowel remaining is jejunum. This would be expected from a consideration of the blood supply, as well as from the greater liability of the distal bowel to disease generally and to gangrene from mechanical causes.

A resection of 6 ft. (1.8 m.) is taken by most authors as the minimum qualifying for the term extensive or massive. When less than this is removed the problem of later metabolic upset, in the absence of other disease, never seems to arise. One patient of Jerould and Washburn's (1929) had only 6 ft. (1.8 m.) resected for polyposis and later had diarrhoea after milk or anything containing fat, but there may well have been polyposis of the

remaining bowel. In their other case the distal 19 ft. (5.8 m.) was resected for mesenteric embolism, leaving 10 ft. (3 m.), and the patient gained weight and was perfectly well two and a half years later. Comparatively few of the cases reported are as informative as this one about the late effects of resection. Most reports give no indication of how much or which part of the small bowel remained; in a few some chronic disease such as tuberculosis makes it impossible to regard the patient as having merely a shortened intestine, and many were followed for a few weeks only. For one or more of these reasons most of the case reports studied do not help greatly in trying to correlate the extent of removal with the late result.

However, the following cases of resection for conditions which would be expected to leave a shortened but otherwise healthy bowel are worth noting. Littlefield (1919) resected the proximal 13 ft. (4 m.), leaving only 6 in. (15 cm.) of jejunum and 4 ft. 1.2 m.) of ileum: the patient was in good health three months later. Sinclair (1924) resected the middle 12 ft. (3.7 m.), leaving several feet above and below, with perfect health three years later. Brenizer (1929) removed the distal 9 ft. (2.7 m.), leaving 6 ft. (1.8 m.), with good health a year later. Holman (1944) removed the distal 19 ft. (5.8 m.), leaving a few feet only, with good health one and a half years later. Cosh (1944) reported a death from diarrhoea and inanition eight months after resection of an unknown length but with only 3 ft. (0.9 m.) of jejunum remaining. Cogswell (1948) resected the distal 10 ft. (3 m.), leaving only 14 in. (36 cm.) of jejunum, with fair health but some diarrhoea six months later. These are representative cases, selected for mention because the reports of them are complete and readily accessible.

Other cases, in which it is not stated how much bowel remained, but with a reasonably long follow-up period, include resections of 11 ft. (3.4 m.) (Turck, 1914), 10 ft. (3 m.) (Turner, 1937), 8 ft. (2.4 m.) (Prioleau, 1944), and 7 ft. (2.1 m.) (Wood, 1920; Watson, 1923), all in good health two or more years later. The loss of 12 ft. (3.7 m.) resulted in poor health and diarrhoea at two months (Brougham, 1907) and at four months (Prioleau, 1944), but in good health with only occasional diarrhoea at 10 months (Addison, 1917). From these and other accounts it seems that diarrhoea in the early weeks is common after the longer resections, with a strong tendency to improve as the months pass. Weight loss, as would be expected, accompanies the diarrhoea and recovers with it. Tetany has occurred in several cases.

Results in the Literature

Collected series from the literature have been published from time to time. Flint (1912) presented 59 cases and Haymond (1935) no fewer than 257. Haymond gives many references, and includes tables of pathology, age, sex, length of resection, type of anastomosis, period of survival, and results in terms of function. Unfortunately, owing to lack of details in the original reports, each table deals with only a proportion of the cases, and few conclusions can safely be drawn from the figures. The condition of only half the survivors had been reported upon three months or more after operation. It is significant of the incompleteness of the information available to him that Haymond was not able even to consider the influence on the result of the anatomical part of the small intestine resected or of the length of intestine remaining—two factors which are likely to be of major importance.

It is clear that considerable variation exists in the response to removal of a large part of the small intestine. Brenizer (1929) stated: "We must conclude that the minimum extreme resection may fail in time and the maximum offers good results, and that there are always possibilities for good and bad between the two extremes." This is true so far as it goes, but the possibility for good is a very strong probability when the resection is not much above 6 to 8 ft. (1.8 to 2.4 m.), or when some 6 to 8 ft. (1.8 to 2.4 m.) is known to remain, and the chances diminish only as these limits are passed. There is certainly an important element of unpredictable and individual variation, but the final result depends to a very great extent on the length of bowel left to the patient.

The actual length of the bowel resected is of much less importance than the fraction it represents of the whole, just as the functional result of a limb amputation depends on how much remains and not on what has been removed. However, perhaps rather naturally, because of the positive nature of this measurement and the dramatic appeal of the very long resections, a disproportionate amount of attention has been given to such lengths as measured. The competitive spirit is exemplified by one author who, having removed 11 ft. (3.4 m.), claimed that this was not only the most extensive resection on record for mesenteric thrombosis, but also the second largest for any cause in the American literature and the tenth largest in the entire literature. Length-resected, as an isolated observation, is of course of some importance, as in certain circumstances it may not be practicable to ascertain how much bowel has been left.

A surgeon finding himself obliged, at such an operation, to remove 15 ft. (4.6 m.) of small bowel can only hope his patient has at least an average length of it. This is usually taken as 22 ft. (6.7 m.), the range of variation being from 15 to 32 ft. (4.6 to 9.8 m.) (Brenizer, 1929). Exceptionally, a healthy small intestine may measure less than 15 ft. (4.6 m.) and it is well known that in some cases of chronic jejuno-ileitis of the "total" rather than the "regional" type extreme shortening occurs. In a case of this kind, not reported here, which recently came to necropsy, the whole small intestine measured only 6 ft. (1.8 m.) in length. The measurement of a contractile muscular organ such as the small intestine is obviously a difficult matter. Spasm reduces it considerably, which was very evident during the operation on Case 2, below. The length of jejunum not requiring removal was marked off and noted to measure between 4 and 5 ft. (1.2 and 1.5 m.); when ready for anastomosis it was so obviously shorter that it was re-measured and found to be only just over 3 ft. (0.9 m.). Clamping of the mesentery and the manipulations involved in resecting the distal intestine were presumably responsible for the shortening.

Case 1

A man aged 29 was seized with violent abdominal pain at 8 p.m. on July 6, 1939, and admitted to the Bristol Royal Infirmary the following afternoon. He was cold and appeared very ill, with a pulse rate of 144. He obtained some relief from his pain by sitting up, a position he insisted on maintaining while being examined. His abdomen was rigid and tender. There was a history suggesting a chronic duodenal ulcer of several years' duration, and a diagnosis of "probably perforation" was made. Some doubt was felt on account of the position of relief from pain which he adopted, also because of his restless movements. He was given

morphine and intravenous saline, and after four hours his condition, though still very poor, had improved enough to allow operation.

Operation.—This was performed on July 7, 23 hours after the onset. The peritoneal cavity contained blood-stained fluid. The stomach was large. There was no perforation, only a healed duodenal ulcer with scarring and stenosis. The lower abdomen was filled by black coils of small intestine, which had passed from right to left through a slit, apparently congenital, in the mesentery. The margin of the aperture was divided so that the coils of bowel could be withdrawn. There was no difficulty in judging them non-viable from their appearance and from the absence of pulsation in the mesenteric arteries. The affected bowel was resected, leaving behind a few inches of ileum and 4 to 5 ft. (1.2 to 1.5 m.) of jejunum. After cutting away its mesentery the resected bowel was found to be just over 14 ft. (4.3 m.) in length. The cut ends of the remaining bowel were closed and the jejunum was anastomosed side to side with the caecum. The patient's condition continued to cause anxiety for several days after the operation.

During convalescence he was greatly troubled by diarrhoea, up to 10 times daily, which was unaffected by drugs or changes of diet. On discharge from hospital, five weeks after operation, he weighed 85 lb. (38.5 kg.), compared with his normal 130 lb. (59 kg.). He continued weak and generally unwell for some weeks, but gradually improved and the diarrhoea lessened. Three months after operation his condition was fair and the bowels acted only three or four times a day. He was, however, getting increasing symptoms from his duodenal ulcer. A radiograph showed that this was active, and that the meal passed rapidly to the caecum. He improved with medical treatment, and five months after operation was in much better health. Ulcer symptoms then recurred more severely than ever.

He was admitted to another hospital, where partial gastrectomy was carried out six months after the first operation. This was in the early months of the war, when some confusion existed, and it does not appear to have been known at the second hospital that most of the small intestine had been removed. He made an excellent recovery and returned home well a month later. The diarrhoea had by this time entirely ceased, the bowels acting on an average once daily with an occasional day missed. It was not until after the war that an attempt was made to trace this patient. Unfortunately it has not been possible to examine him, but he is known to have been in good health and at work in December, 1949, more than 10 years after resection of the small intestine.

Case 2

A married woman aged 41 attended the Bristol Royal Infirmary with a carcinoma of the caecum, for which a right hemicolectomy was carried out on October 28, 1948. A chain of carcinomatous glands had to be dissected off the superior mesenteric vessels. She remained well for a year, but another mass then appeared in the right iliac fossa and she was readmitted to hospital.

Operation.—On December 9, 1949, the recurrent mass was excised with the iliacus fascia, right ureter, and external iliac artery. Metastatic spread was, as at the first operation, confined to the mesenteric glands, but this time they were so bound up with the superior mesenteric vascular trunk that dissection was out of the question. The superior mesenteric artery and vein were divided clear of the highest affected gland, and the mesentery, with the devascularized small intestine, was excised in a block with the main tumour mass. The resected bowel was later measured and found to be 11 ft. (3.4 m.) in length. Between 4 and 5 ft. (1.2 and 1.5 m.) of jejunum remained, and 1 in. (2.5 cm.) of ileum, the latter being just proximal to the end-to-side anastomosis of ileum to transverse colon carried out at the original hemicolectomy. Continuity of the alimentary canal was restored by end-to-end anastomosis of the jejunum to the stump of the ileum. Recovery was uneventful.

During convalescence there was little trouble with diarrhoea. At first there were three stools daily, but after three weeks they were reduced to two. No drugs were given, but a diet high in carbohydrate and protein and low in fat was found to be most satisfactory. The stools were never more than semi-formed, and, unless fat was kept to a minimum, were pale and obviously fatty. Her weight on leaving hospital a month after operation was steady at 98 lb. (44.5 kg.), compared with 120 lb. (54.4 kg.) before operation, and she felt remarkably well. The tendency to looseness of the bowels diminished and she gradually found herself able to take the ordinary meals of her home, avoiding more than a minimum of green vegetables. She slowly regained weight, and two months after the operation weighed 103 lb. (46.7 kg.), the bowels acting twice daily. She felt very well and was already doing all her housework. Seen at intervals, she continued well and appeared to be in excellent health in November, 1950. Shortly afterwards she began to feel discomfort in the right iliac fossa. When examined a little over a year after the operation a hard fixed mass was palpable, without doubt a further recurrence of growth.

Discussion of Cases

In Case 1 it was obvious how much intestine would have to be removed. It seemed a great deal, but there was no alternative. In Case 2 the decision was a much more difficult matter. Less radical, but still perhaps adequate, surgery for the malignant glands would have permitted the leaving of twice as much small intestine. It would have been possible to enucleate the uppermost of the affected glands, instead of taking them in a block with the rest, and so to divide the superior mesenteric vessels more distally. In both cases the opportunity was taken to estimate the length of bowel remaining. The first patient was so ill that the estimate was made only by the appearance of the bowel coils *in situ*. In Case 2 the bowel was carefully examined and the measurements were as accurate as those of living bowel are likely to be. The shortening of the residual bowel which occurred from muscular contraction has already been mentioned. The length remaining was of the same order in both cases, if anything less in Case 2. This patient had a rather shorter small intestine originally, so that the proportion removed was about the same in both.

Case 1 certainly had a great deal more trouble with diarrhoea in the post-operative period and was in real distress from this for some weeks. His case was complicated by the presence of a duodenal ulcer. The diarrhoea, which had already lessened, was completely relieved after the partial gastrectomy. Case 2 might have been expected to have more trouble with diarrhoea than she did, seeing that she had previously lost the right half of her colon. A striking contrast between the two patients was in their personalities. Case 1 was throughout a difficult patient, anxious and always complaining. Admittedly he had reason to be so in his severe illness, but Case 2 was the exact opposite, quietly determined to get well and with never a complaint from start to finish. It is possible that an unusually stable nervous system was a factor in the mildness of her intestinal symptoms and in the rapidity with which physiological adjustment took place.

Conclusions

Removal of more than three-quarters of the small intestine is likely to be followed by serious permanent effects, but there is considerable variation between individuals. Up to one-half of the intestine can be resected without fear of metabolic disturbance.

If the circumstances preclude an estimate of one half, then 6 ft. (1.8 m.) can be considered safe to remove. Except when the small bowel is shortened by disease it is rarely less than 15 ft. (4.6 m.) in length.

In the more extensive resections it should be possible to estimate the length of the remaining bowel. To leave 8 to 10 ft. (2.4 to 3 m.) is ample, and the taking of the slightest risk in order to leave more cannot be justified, while 5 ft. (1.5 m.) or less may be enough for subsequent good health.

Tetany should be watched for as a possible post-operative complication.

The general tendency is for health and weight to improve, and for diarrhoea to lessen, with the passage of time.

Extensive resections give better results than one might expect, and should not be allowed to fail through being insufficiently radical.

Summary

Extensive resections of the small intestine are discussed and an attempt is made to give some guidance on how much can be removed in certain circumstances. Emphasis is placed on the proportion of the whole removed, and the amount left behind, in determining the result, rather than on the actual length resected. Two new cases are reported in which the result was satisfactory ten years and one year after a resection of the order of 70%. In each of them some 4 to 5 ft. (1.2 to 1.5 m.) of small intestine remained.

At the Royal Society of Tropical Medicine, on December 13, Dr. D. B. Jelliffe, senior lecturer in medicine, University College, Ibadan, Nigeria, speaking on the African child, described a form of infective gangrene of the mouth which differs from cancrum oris, since it infects the bones. This terrible and destructive disease, which may strip the tissues from half the side of the face, can be cured by penicillin if taken early, but, although in such cases a remarkable degree of replacement of lost tissue takes place, there is usually gross permanent disfigurement. The aetiology is not clear, but infection and malnutrition must both be important. The newborn baby may have to share his mother's (or grandmother's) milk with a brother 2 or 3 years old, and the milk may be thin, though often unexpectedly rich in protein. Congenital syphilis and relapsing fever are common, and congenital deformities, appearing with a frequency about that observed in Europe, lead not rarely to a fatal bronchopneumonia. The estimated infant mortality rate in Nigeria is somewhere between 300 and 500 per 1,000 live births.

ORCHITIS IN BORNHOLM DISEASE

BY

R. J. G. MORRISON, M.D., M.R.C.P.

Lieutenant-Colonel, R.A.M.C.

AND

J. P. BAIRD, M.B., M.R.C.P.

Major, R.A.M.C.

Medical Specialists, the Queen Alexandra Military Hospital, Millbank, London

In the light of the reported widespread outbreak of Bornholm disease in this country an account of its occurrence in a family and in a contact may be of interest, since epididymo-orchitis figures prominently as a complication.

That Bornholm disease may affect several members of a family is well known. Dabney (1888) describes a family of six children, five of whom had the disease; Payne and Armstrong (1923) cite a family of ten, all developing symptoms within a fortnight; and further examples are given by Pickles (1933), Sylvest (1934), and Howard (1938).

The incidence of orchitis differs markedly in the various epidemics. Sylvest (1934) gives a good account of epidemic myalgia. He states that orchitis was first described as a complication by Bacher in 1896. He reviews the literature and reports 93 personal cases, only one of which had orchitis. Jamieson and Prinsley (1947) describe orchitis as the commonest complication of an outbreak at Aden. It affected 12 out of 30 male cases and was usually unilateral. Orchitis appeared between the 8th and 36th days. The duration of pain and swelling was two to six days, but in one case it was ten days. Huss (1934) states that in the Swedish epidemic of 1931 the incidence of orchitis was 50 in 884 cases. He quotes three further outbreaks with orchitis, notably one at Håby in 1931 in which an epidemic of "benign orchitis" was followed by typical myalgia. On the other hand, Scadding (1946), giving an account of an outbreak in the Middle East, makes no mention of orchitis in his cases. We can find no direct reference to this complication occurring in members of a family.

Case 1

A 52-year-old officer was taken ill on September 17, 1951, just after returning from a three-weeks holiday with his family in Devonshire. (Cases of Bornholm disease had occurred in the locality but had not been associated with orchitis.) He felt shivery and unwell and ached all over. His temperature was 103° F. (39.4° C.). Pain in the left side of the chest appeared on the 20th, and next day had spread across the front to the right. This was severe on moving or deep breathing. He was treated at home by his family doctor. On October 3 he returned to work, but aching pain started in the left testicle and lasted for 48 hours. On October 6 the pain had appeared in the right testicle, and by the 9th discomfort was acute and the organ had become swollen. On October 12 the pain across the chest returned, pleuritic in type and more severe on the right side. Next day he was admitted to hospital. His past history included the usual childhood ailments, mumps, paratyphoid, and malaria.

On examination there was no fever, but he was in some discomfort, complaining of pain in the right side of the chest and in the right shoulder. There was diminished movement of the right lower chest and at the right base air entry was

diminished. Pleural friction was heard over a small area below the right nipple. The blood pressure was 220/140. The right testis and epididymis were swollen and acutely tender. On routine examination the urine was normal. The leucocytes numbered 6,700 (polymorphonuclears 53%, lymphocytes 46%, eosinophils 1%). A chest film showed some tenting of the right leaf of the diaphragm, together with some haziness of outline. Serum agglutinations were negative for leptospira, typhoid, and brucella groups. Specimens of serum were sent to the Virus Reference Laboratory, Colindale, for tests against the Coxsackie virus. The chest pains had practically gone by October 17, although the right testicle and epididymis were still swollen but not tender. All abnormal signs had passed off by October 20, and the patient was discharged fit on the 22nd.

The family consisted of his wife and three sons. One, aged 22, on September 4 complained of indigestion and a rash, thought to be due to something he had eaten. He recovered in four days, but on September 14 he became ill again with fever, shivering, and pain in the shoulder and over the left lower ribs on deep breathing, sneezing, or coughing. Towards the end of his illness he had pain in both testicles, the left beginning first and becoming swollen. His illness lasted 14 days in all.

The second, aged 19, was taken ill on September 14 with headache, malaise, and pains over the lower ribs on both sides. Headache and photophobia were severe and his fever continued until the 27th. Towards the end of his illness pain developed in both testicles.

The third, aged 15, became ill on September 12 with nausea, malaise, and aching pains across the front of the chest. He had fever for a few days but made a rapid recovery. There was no testicular pain or any suggestion of orchitis.

The wife had a sore throat, beginning about the middle of September, but she remained well otherwise.

Case 2

A middle-aged officer had been closely associated with Case 1 since the latter returned from his holiday. On October 1 he became ill with fever, sore throat, and cough. There was no pain in the chest. Pyrexia and malaise lasted for one day only, but on October 4 he complained of pain and swelling of the right testicle. He was seen as an out-patient on the 8th, when the right testis was found to be normal but the epididymis was enlarged and tender. On the 10th there was a definite orchitis: Intermittent testicular pain and swelling persisted. Considerable enlargement and much tenderness of the testis and epididymis continued until October 24. From then onwards symptoms resolved.

Summary

The importance of orchitis as a complication of Bornholm disease is stressed.

This cause should be considered in cases of epididymo-orchitis of undetermined aetiology, particularly if the condition appears in epidemic form.

Orchitis should be looked for in cases of Bornholm disease, especially in the second week.

Our thanks are due to Dr. S. J. Darke, of Hounslow, for clinical details concerning the family, to Colonel F. J. O'Meara, and to the Director-General, Army Medical Services, for permission to forward these notes for publication.

"TRIGGER-THUMB" SIMULATING PARALYSIS

A REPORT OF TWO CASES

BY

ANDREW ZINOVIEFF, M.R.C.S., L.R.C.P.

*Late Physician-in-Charge, Department of Rehabilitation
and Physiotherapy, United Oxford Hospitals*

Recently two patients have been seen who appeared at first to have an isolated paralysis of the flexor pollicis longus.

Case 1

A housewife aged 53 suddenly noticed that she was unable to flex the terminal joint of her left thumb. She had not had any previous symptoms in the thumb, and her only other complaint was of some acroparaesthesiae in both hands. When first seen, some months later, the only detectable abnormality was loss of active flexion at the terminal joint of the thumb, though passively it appeared full, with some springy resistance at the limit. Faradic stimulation of the flexor pollicis longus produced a flicker of movement at the terminal joint.

General medical examination and an x-ray film of the thumb showed no abnormality. A tentative diagnosis of "hysterical paralysis" was made, and treatment by faradic stimulation and by attempts to re-establish active movement was begun.

The patient tried hard to achieve movement for about three weeks, and then suddenly she found that, with great effort and with pain felt in the anterior metacarpo-phalangeal region of the thumb, she was able actively to flex the terminal joint through a full range, but that it then became fixed in flexion and could not be straightened except passively, when a palpable click was noticeable at the site of pain. It was now evident that the diagnosis was "trigger-thumb" involving the flexor pollicis longus, and that the obstruction to movement which was occurring at the level of the metacarpo-phalangeal joint had been partly overcome.

Incision of the tendon sheath was advised, but during the usual long delay before admission the patient continued to practise flexing her thumb, and this gradually became easier and less painful, and eventually spontaneous recovery occurred, so that no disability remained. When seen 18 months later she complained only of odd twinges of discomfort in her thumb, but no catching. There was full painless active movement of the interphalangeal joint. Slight enlargement was palpable in the line of the sheath and tendon of flexor pollicis longus at metacarpo-phalangeal joint level, and a slight click was noticeable here on active flexion-extension of the terminal thumb-joint.

Case 2

A housewife aged 55 suddenly found that she was unable to flex the terminal joint of her left thumb. When seen at another hospital, where a diagnosis of hysterical paralysis was made, she was referred to a psychiatrist, who was unable to find any evidence of psychological disturbance. When seen at this hospital some weeks later she was still apparently unable to bend the tip of her thumb, and her only other complaint was of slight acroparaesthesiae in the left hand. On going into her history in more detail it was found that the onset of the condition occurred when she woke up one morning with the thumb flexed at the terminal joint and had had to pull it straight. Subsequently she had been unable to bend it at this joint, except on two occasions

when she had fallen with the thumb bent under her, again causing the terminal joint to become fixed in flexion and requiring manipulation to pull it straight.

On examination it was found that active flexion of the terminal joint of the thumb had not been completely lost, for with the proximal phalanx held firmly a flicker of active flexion was noticeable, and, furthermore, this could also be reproduced by faradic stimulation of the flexor pollicis longus. Passively, flexion was full, but with a springy resistance at the limit. Some tender enlargement in the line of the sheath and tendon was palpable at the metacarpo-phalangeal-joint level, and the anterior border of the base of the proximal phalanx seemed unduly prominent. There was a suggestion of creaking at this level on attempted flexion of the terminal thumb-joint. An x-ray film of her thumb showed no abnormality.

The patient continued repeatedly to try to make her thumb bend. After a few minutes there was a sudden sensation of tearing, and almost full active flexion of the terminal joint was restored. It was now accompanied by coarse creaking in the position of the tendon sheath at the metacarpo-phalangeal-joint level. The diagnosis was thus again established as "trigger-thumb," the obstruction being overcome by force. She was able to keep the movement of the terminal joint of the thumb for the rest of the day, but by next morning it was again quite stiff. When seen several weeks later the condition was unchanged, and, what is more, she was beginning to develop a similar condition in the opposite thumb. In this case, however, it was proceeding along more classical lines, for she was having difficulty in both bending and straightening the terminal joint, and this was associated with a "click," most noticeable on extension, and located at the usual metacarpo-phalangeal-joint level.

Tendon-sheath incision was suggested for her left thumb, but she was not keen on this, and so was advised to go on trying to re-establish normal movement of the tendon. She was seen three months later, when her left thumb was improving in that, although fixed in extension first thing in the morning, with active exercise it soon regained normal mobility, though this was associated with some clicking in the line of the tendon sheath. The right thumb at this time presented a similar picture.

She was finally reviewed after a further nine months, when she said that both her thumbs were quite normal, and, indeed, on examination the only slight abnormality was some palpable enlargement in the line of the sheath and tendon of the flexor pollicis longus, on both sides, at the metacarpo-phalangeal-joint level.

Discussion

In adults "trigger-finger" affecting the ring and middle fingers is more common than "trigger-thumb." The usual clinical picture is that of a sudden onset of difficulty in bending and straightening the terminal joint, but the difficulty is experienced in semi-flexion. It is associated with a click or jerk palpable in front of the metacarpo-phalangeal joint, for this is the level at which the obstruction commonly occurs (Croft, 1937; Wiles, 1949).

In more advanced cases the obstruction may have to be overcome by passive stretching, and extension usually causes more difficulty than flexion, so that the terminal joint tends to become fixed in the flexed position. In these cases the diagnosis presents no difficulty. "Trigger-thumb" is particularly common in infancy and childhood; and is frequently bilateral; it may be present from birth. Case reports, which are not numerous, appear to be confined to this group (Compere, 1933; Hudson, 1934; Jahss, 1936; Zadek, 1942; Rose, 1946; Sprecher, 1949). The signs are similar to those of the adult group, but the presenting symptom is commonly that

the child's thumb has become fixed in flexion. No report could be found of the terminal joint becoming fixed in extension.

The obstruction may be caused either by enlargement of the tendon or by enlargement of the tendon with narrowing of its sheath in front of the metacarpo-phalangeal joint. The former factor alone appears to be by far the more common one. This feature distinguishes the pathology of "trigger-finger" and "trigger-thumb" from that of stenosing tenosynovitis occurring at the radial styloid (de Quervain's disease). In this, the narrowing of the canal within the sheath by the effects of inflammation of the sheath is the important cause of the symptoms and signs (Keon-Cohen, 1951). In "trigger-finger" or "trigger-thumb," however, inflammation of the sheath is not usually seen, and Sprecher found no such evidence in 12 cases.

The consensus is that conservative treatment is of very doubtful value and that surgery in the form of vaginotomy is the only really effective and rapid cure.

The two cases in middle-aged women reported here are unusual in that the real diagnosis was masked because the terminal joint of the thumb had become fixed in extension. At first, as all too often happens when no obvious organic lesion can be discovered, a diagnosis of hysteria was made. In the first case the diagnosis was elucidated by the patient's own effort; in the second, foreknowledge of the syndrome helped to solve the problem. It was fortunate, from the latter patient's point of view, that the psychiatrist was unable to detect any psychological abnormality. In establishing the diagnosis at an early stage, the springy feel at the limit of flexion, due to buckling of the tendon of the flexor pollicis longus distal to the obstruction, and the palpable enlargement of the tendon and sheath at the metacarpo-phalangeal level are useful signs. The complete spontaneous recovery of both cases is in keeping with the prognosis for the more common types of this lesion in adults (J. C. Scott, personal communication). However, as it takes many months to recover spontaneously, incision of the tendon sheath as a method of quick relief in those in whom the functional disability is troublesome should be considered. Physiotherapy, except for attempts by the patient to break down the obstruction by repeated active movements, is of no use.

Summary

Two unusual cases of stenosing teno-vaginitis of the flexor pollicis longus simulating paralysis are described.

Hysteria was initially diagnosed, and one case was actually sent to a psychiatrist.

Spontaneous and complete recovery occurred in both, but it took many months.

Physiotherapy, other than repeated active movements on the part of the patient, was not of value.

I am indebted to Mr. Peter Wright for reviewing the second case.

Medical Memoranda

Gangrene of Unknown Aetiology in the Foot

Gangrene of the extremities is rare in infancy and childhood. In older children it seems to occur rather more commonly than in infants, and the cause is less obscure.

A number of cases reported have followed acute exanthemata and other general infections. Scarlet fever has been particularly indicted, and Hoyne and Smollar (1941) reviewed 15 such cases. Others have followed measles (Winstead, 1935) and chicken-pox (Watson, 1934), while Martin and Shore (1928) reviewed the literature and found cases following typhoid, typhus, measles, scarlet fever, diphtheria, pneumonia, appendicitis, tonsillitis, and pulmonary tuberculosis. Uhr (1838) found pneumococcal septicaemia in his case. In a series of 50 cases in infants and children reviewed by von Khautz (1914) 39 followed infections. Thrombocytopenia in association with infections has resulted in peripheral gangrene in children. This occurred with scarlet fever in the case of Webb *et al.* (1947) and with chicken-pox in that of Stoesser and Lockwood (1939).

Few cases have resulted from emboli. In a review of such cases, Craig and Muns (1931) reported the case of a child in whom gangrene was due to emboli from aortic stenosis. In von Khautz's (1914) series four were presumed to be due to Raynaud's disease. Lawrence and McCance (1931) described a child with diabetes causing peripheral gangrene. Other causes are frost-bite, trauma, ergot poisoning, local infections, and periarteritis nodosa. Bandages and plaster casts applied too tightly and weights tied to the foot to assist the delivery of infants have all caused local gangrene.

Peripheral gangrene in association with the presence of cold agglutinins in the serum has been reported in an adult by Stats and Bullowa (1943). Presumably the arterioles were plugged by agglutinated red blood cells. Gangrene may occur in association with paroxysmal haemoglobinuria, and this has long been known to occur in the absence of syphilis (Johnson, 1894).

Except in cases of emboli and arterial spasm, peripheral gangrene must be assumed to be due to thrombosis following arteritis consequent upon some other condition. Arteritis has been proved histologically by Martin and Shore (1928) and Hoyne and Smollar (1941).

The following case is reported because of the mildness of its course and the complete lack of aetiological factors.

Case Report

A boy aged 8 was well until March 12, 1950, when he appeared listless. After a restless night he was still listless, and also off his food but thirsty. In the afternoon he complained of some pain in his right big toe. This appeared bluish-red and swollen, and some reddish patches on the medial surface of the leg were noticed. On March 14 his condition was much the same, but at midday he had a major convulsion lasting about an hour. There was no history of trauma to the foot, and his shoes were free from protruding nails. Later in the day he was admitted to hospital.

Apart from pink disease when aged 2, and recurrent attacks of bronchitis in the past two years, he had had no illnesses.

On admission he was flushed and looked extremely ill. Temperature 103.5° F. (39.2° C.), pulse 128, respirations 26. Lips and tongue dry, tongue also furred. Ears, throat, neck, and chest normal. Heart: cardiac impulse forceful; apex beat in fifth space in mid-clavicular line. Heart sounds muffled; short soft systolic murmur audible at apex. B.P. 110/70 mm. Hg. Abdomen, arms, and left leg normal. Right leg: big toe black, swollen, and tender in distal two-thirds; felt same temperature as corresponding toe of other foot. Plantar surface of fourth toe similarly affected. Plantar surface of fifth toe and area about 1 in. (2.5 cm.) in diameter on lateral border of the foot blanched and cold. Four dark-red, slightly raised, hot areas measuring 0.5 to 1 cm. in diameter on dorso-lateral surface of foot (Fig. 1).

FIG. 1.—Condition of foot on March 18.

FIG. 2.—Condition of foot on May 4.

Several red streaks on medial side of lower part of leg. Four small pustules on lower part of leg and foot and one large pustule on left buttock. Lymph nodes in groins not enlarged. Pulsation normal in all palpable arteries, felt in entire length of dorsalis pedis artery of affected foot. No difference in circulation detected between the two legs on raising and lowering them.

Investigations.—Hb, 11 g.%; W.B.C., 9,000 per c.mm. (neutrophils 86%). Urinalysis: protein 90 mg. per 100 ml.; scanty cellular and granular casts, epithelial cells and erythrocytes in centrifuge deposit. Rothera's test, slight positive. Benedict's test, negative. Blood sugar (mid-morning), 144 mg. per 100 ml. Cold haemagglutinins: negative. Blood W.R., negative. Blood culture (10 days), sterile. Pus from pustule on dorsum of foot gave scanty staphylococci (coagulase-negative). X-ray film of foot (repeated after three weeks), normal. X-ray film of chest, normal. Tuberculin reaction (jelly test), negative.

In view of the heart murmur, the diagnosis made on admission was acute bacterial endocarditis. The patient was therefore treated with crystalline penicillin, 2,000,000 units daily for nine days, and sulphadimidine, 12 g. daily for six days. The general condition rapidly improved, and after five days the cardiac murmur had disappeared. The fever reached 99–100° F. (37.2–37.8° C.) after two days, but did not completely settle to normal for 10 days. The preliminary diagnosis was discarded after nine days in hospital, but penicillin therapy was continued for another 16 days (procaine penicillin-aluminium stearate, 300,000 units daily). After four days in hospital an enlarged tender lymph node was felt in the right inguinal group. The gangrenous areas did not spread, but gradually became blacker. The blanched and reddened areas also gradually blackened. All areas were kept dry, but the big toe slowly became fluctuant, and after 10 days began to ooze a mixture of pus and altered blood, which was sterile on culture.

On the 22nd day after admission the nail and surrounding tissue were removed to allow egress of this material. Repeated blood counts during this time showed a range of 8,500 to 11,500 leucocytes per c.mm., with 54-69% neutrophils. Subsequent urinalyses were all normal. The other gangrenous areas gradually separated after the 30th day in hospital, and by the 42nd day they had all separated, leaving clean granulating surfaces (Fig. 2). In none of these areas was separation deeper than the subcutis. They were dressed with petroleum jelly gauze, and all healed over the course of the ensuing 10 weeks. The gland in the right inguinal region did not break down, and gradually subsided. The patient was discharged from hospital on the 58th day after admission, surveillance being continued in the out-patient department. A small protrusion of the distal phalanx of the big toe sequestered 10 weeks later. No regrowth of the nail has occurred.

Comment

In the case here reported no association or predisposing factors could be determined. The history did not suggest a previous generalized infection. There was some support for a diagnosis of local infection in the presumed fever before admission to hospital and the convulsion, which must be assumed to have been febrile in origin. The lymphangitis in the leg and the later development of an enlarged tender lymph node in the groin also lent support to this diagnosis, but these may have been secondary to the pustules on the foot and leg. The distribution of the gangrene did not, however, suggest a local infection. The normal leucocyte count was also against an infection, and osteomyelitis of the tarsus was excluded by radiography.

Arteriosclerosis and thromboangiitis obliterans could be excluded in view of the age, and there had been no previous episodes to suggest a diagnosis of Raynaud's disease. The course of the illness did not suggest a diagnosis of periarteritis nodosa. Diabetes and syphilis could be almost certainly excluded. There was no haemoglobinuria and the serum was negative for cold haemagglutinins. No history whatever of trauma could be obtained, and frost-bite was out of the question.

Thus none of the accepted associated or predisposing factors in the causation of peripheral gangrene could be demonstrated in this case. The evidence leans more towards a local infection than any other aetiological factor.

Thanks are due to Professor R. S. Illingworth, who gave permission for the publication of the case report and for his encouragement and advice in the preparation of this paper.

An Anomaly of the Sedimentation Rate in Rheumatic Diseases

In view of the extent to which the Wintrobe sedimentation rate is now being used in the rheumatic diseases, in particular for the assessment of steroid hormone treatment, it was thought that it would be useful to record in a preliminary note an anomaly we have observed, since it may be very misleading in such trials. A full account, it is hoped, will be published in the near future. It would appear from the paper published recently by Gilmour and Sykes (1951) that the phenomenon may not be confined to the rheumatic diseases.

In this unit during the past 10 months, largely owing to our participation in the Medical Research Council United States-United Kingdom scheme for the treatment of rheumatic fever with cortisone, etc., we have determined simultaneously the sedimentation rate by the Wintrobe and the Westergren methods. In some cases an anomaly in the sedimentation rate has been noted in that the Westergren method has given a very high recording, whereas, with blood taken from the same syringe, the Wintrobe method has given readings falling within the normal range or only slightly above it. The Westergren rate was a better index of the clinical state. The Westergren readings were virtually unaltered when dry sodium citrate was used instead of citrate solution as the anticoagulant. The following simultaneous weekly readings taken from a patient with disseminated lupus erythematosus illustrate the type of discrepancy that has been encountered.

Westergren readings (mm./hr.): 75, 84, 65, 43, 35, 36, 57, 98, 60, 90, 90.

Wintrobe readings (mm./hr.): 6, 5, 6, 5, 5, 14, 5, 16, 12.

The haematocrit readings on these occasions ranged from 40 to 43.

As most cases here are in-patients for prolonged periods, we have been able to observe the incidence of this anomaly and have attempted to correlate it with the clinical state. Cases showing this anomaly are those of Still's disease, rheumatoid arthritis, and disseminated lupus, and, very occasionally, acute rheumatic fever at the onset of the attack. In some cases the anomaly occurs consistently over several weeks. In other cases the phenomenon occurs sporadically. When it is noted, sedimentation rates are repeated in duplicate.

The clinical state of patients showing this discrepancy would lead one to expect a high sedimentation rate. In the example quoted the patient was febrile, had arthritis and a lupus rash, was losing weight, and had leucopenia.

In the cases showing these discordant readings, similar low values are obtained when heparin is used as an anticoagulant and the blood set up in either a Wintrobe or a Westergren tube. The addition of dry citrate to the previously oxalated or heparinized blood causes the sedimentation rate to rise to a level approximating that obtained with the Westergren method. Further investigation of the mechanism is proceeding. It appears probable that it depends on the anticoagulant's effect upon the pH.

The cases in this unit belong to a selected group (rheumatic diseases) in whom it is apparent that this phenomenon is not uncommon (10 out of 86 cases). It is not known yet to what extent this phenomenon occurs in other diseases. In the rheumatic diseases, at least, the assessment of activity by the Wintrobe method may be misleading.

Reviews

GENETICS AND THE EYE

Genetics in Ophthalmology. By Arnold Sorsby. (Pp. 265; 236 figures. £2 2s.) London: Butterworth and Co. 1951.

With the single exception of serology, ophthalmology affords better opportunities for useful genetic study than perhaps any other branch of medicine. The relative ease with which observations can be made on those still living, the profusion of hereditary anomalies of all kinds, the strikingly high proportion of conditions in which transmission is uncomplicated, all contribute to this pre-eminence. It is indeed true that almost the whole of medical genetics can be expounded by means of ophthalmological examples; but there is more to it than this; for in a country like our own at the present time, thanks to the conquest of infection, the proportion of blindness and ocular disease due to genetic causes is very high indeed. This is emphasized in Professor Sorsby's book; he supports the view, for example, that such conditions as glaucoma and senile cataract have a hereditary basis. If, then, any branch of medicine justifies a genetic textbook of its own, this is the subject of choice.

The first part of the book is on general principles. Some might think that it would be better to refer the reader to a general textbook, but surely Professor Sorsby is right in undertaking the task himself. Inevitably, perhaps, this is the least successful section, for space does not permit the argument to be developed at sufficient length. Moreover, Professor Sorsby has rather fallen between two stools. He has been influenced by my own introductory textbook (to which he makes generous reference), in which, for the sake of simplicity, the approach was made strictly deductive; but at the same time has preserved in the main the more usual approach adopted by other writers. Thus he does not get the best out of either method. Nevertheless the theoretical introduction is competently handled even if it is adequate rather than inspired. One important subject, however, is not made sufficiently clear. The reader will not understand from the account of crossing-over on p. 29 that linked genes (it is a pity that the word linkage was ever coined) tend to separate unduly often just as frequently as they tend to be associated unduly often, and so the old error that traits are linked when they tend to occur in association may be perpetuated.

The largest section of the book is on isolated ocular anomalies. Here the author adopts a plan which could be fully successful only in the hands of someone of great experience and knowledge in the pathological, clinical, and genetic fields. He gives his own summing-up for each condition, illustrating it with selected family histories. It will be found a readable and reliable guide. Those with special knowledge of some particular disease may be inclined to question points of detail here and there, but it is a fine summing-up and probably as good as one man could achieve. The research worker will find a straightforward statement and a bibliographic key to the literature.

It is perhaps in the last and shortest section, on generalized disorders with ocular aspects, that Professor Sorsby's mastery of his subject appears most clearly,

for he threads his way skilfully through the difficulties of classification. In this section there is a mistake which ought to be pointed out, as it will puzzle many readers: the pedigree of Fig. 214 suggests ordinary recessive inheritance, not sex-linkage as stated in the legend.

There are 236 figures, beautifully reproduced on good paper; many are in colour. It is an attractive volume and one which should be of great value to ophthalmologists as well as to workers in human genetics.

J. A. FRASER ROBERTS

MOSQUITO BEHAVIOUR

Mosquito Behaviour in Relation to Malaria Transmission and Control in the Tropics. By R. C. Muirhead-Thomson, D.Sc. (Pp. 219; illustrated. £1 10s.) London: Edward Arnold. 1951.

Dr. Muirhead-Thomson gives an account of the results of recent research on the behaviour of anopheles mosquitoes under conditions in nature as studied by modern methods. He discusses in an interesting manner how different species behave when entering and leaving houses, how they select their daytime resting places, what circumstances determine where they shall lay their eggs, and many other features of their behaviour and relations to their environment, together with how all this fits in, or fails to fit in, with methods used for their destruction. Especially interesting to the field worker are his accounts of the many ingenious devices used in modern field research methods in this connexion.

As the author points out, the recent extensive use of residual spraying with D.D.T. and other insecticides has given to every detail of behaviour an importance it did not previously have, so that investigation of behaviour has now become a prime necessity for control. Summarized and presented as a connected story, anopheles behaviour and the methods used in its investigation make an interesting contribution to natural history and a valuable and readily accessible source of information both to entomologists concerned with insect behaviour and to ecologists. To workers interested or concerned in malaria control the importance of this careful study based on wide experience by the author will have a special appeal. The chapter on the relation of behaviour to control by insecticides, including D.D.T. and gamexane in particular, will serve both as a caution and a guide to action. The book is one to be read for interest and pleasure, but reread and studied by every malariologist, for no comparable account has so far been available discussing anopheline behaviour so comprehensively and in such detail.

S. R. CHRISTOPHERS.

ELECTRICAL INJURIES

Fortschritte in der Behandlung Schwerer und Schwerster Hochspannungsunfälle. By Professor H. Fischer and Dr. R. Fröhlicher. (Pp. 72; 23 illustrations. M. 10.80.) Stuttgart: Georg Thieme. 1951.

Following Bywaters's demonstration of myoglobinuria in the crush syndrome, the authors have sought, and found, evidence of myoglobin in the urine of victims of severe electrical high-tension accidents. The pigment is said to be released from muscles by electrothermic action and to act as a nephrotoxin. For treatment they advocate immediate alkali therapy (sodium bicarbonate by mouth or even intravenously) to minimize any renal damage, and early active measures, which included the amputation of two limbs and peritoneal dialysis in the

one case described in meticulous detail. Second-hand reports of eleven other cases are discussed; venesection of as much as one pint of blood is advocated as an adjuvant to the fluid therapy of haemoconcentration. The authors boggle at exchange transfusion.

Now there have been great advances in the general treatment of severe burns—argued so clearly, and applied so successfully, by Colebrook and others—but there has been, presumably, no change in the incidence of renal complications in electrical injuries in particular: they are very rare. While transient albuminuria is common, we found haematuria in only 10 out of some 5,000 cases of electrical injury, and it would disappear spontaneously a few days after the accident. One case alone had 70 ml. of blood in the bladder after a 45,000-V accident and died in complete anuria 48 hours later; both operation and necropsy were refused. In another case renal failure developed in the first 12 hours after a 25,000-V injury, and in a third case, surprisingly, as much as six weeks after a 2,000-V accident. Both recovered promptly after the amputation of an arm and a hand, respectively.

But these were exceptional cases, and conservatism should be the rule in the local treatment of electrical lesions, especially where there is immediate or delayed necrosis, or necrobiosis, of tissues, rather than the frank burn of an arc discharge. For the extent of the former can rarely be appreciated at the beginning, and even extensive injuries may leave the general condition unimpaired. Moreover, progress, albeit slow, is often unexpectedly good. Thus, we have seen spontaneous regression of a cataract resulting from a stroke of lightning, and return to normal function of open elbow joints with gross soft-tissue and cartilage destruction from high-tension currents. But secondary haemorrhage is a very real danger.

Spastic or thrombotic vascular effects will often lead to quite dramatic symptoms (e.g., in the central nervous system) and add to the fascinating variability of electropathology. We have much to learn, but the search for a common denominator, even a nephrotoxic one, is to be condemned when it leads to the abandonment of the well-proved conservative treatment of electrical injuries.

STEFAN JELLINEK.

SMALLPOX

The Diagnosis of Smallpox. Issued by the Department of Preventive Medicine and Public Health, Leeds University. (Pp. 12; illustrated. 2s.) Leeds: H. Grayshon Lumby. 1951.

The clinician—even the expert one—has had good grounds in recent years for re-examining the fundamentals of the diagnosis of smallpox. It is undoubtedly true that in such circumstances a return to the classic work of Ricketts makes the expert aware that it left very little unsaid on the side of clinical observation. But all cannot find refreshment from such a source, and this may be sufficient excuse for the publication of a small booklet which contains the essentials for the clinician. Dr. C. W. Dixon saw a considerable amount of smallpox in North Africa, and the present publication contains the fruits of that experience. There can be no doubt that many of the mistakes in diagnosis arise from the fact that the student has been taught the “classical” sequence of events in smallpox. The impression is thus left that the variola virus, when it attacks the European, produces an almost uniform disease with a characteristic course.

The modern approach to all infectious disease, however, emphasizes the peculiarly personal reaction of the host to parasitic attack; the clinical picture produced is a compound of the “virulence” of the infecting organism and the defences—specific and non-specific—of the patient. Dixon expresses this point by defining nine “types” of smallpox. While this can be a useful device for general teaching purposes, it should not be forgotten that these are in fact merely nine broad stages in the modification of the disease from the most severe—purpura variolosa—to the most mild—variola sine eruptione—and that its greatest usefulness is probably not in any aid to clinical differentiation but as a convenient method of subdividing cases in an epidemic for statistical purposes.

The importance of distribution is rightly emphasized. In most clinical accounts of the disease too much attention has probably been given to a detailed description of the individual lesion in regard to its shape, size, location in the skin, and presence of umbilication. In fact, in examples greatly modified by previous vaccination the individual lesion can be indistinguishable from that of chicken-pox, and in such cases the general and focal distributions are the most important clinical facts.

This booklet is therefore a useful vade-mecum for the practitioner. It contains all the relevant information. It could perhaps have been improved—and not altered in character—if the various points had been grouped together under side-headings. This would have permitted more easy reference without interfering with the author's intention of keeping the booklet small and essentially clinical in its application. Readers in Scotland should note that specimens for examination should be sent either to Dr. Swain, Department of Bacteriology, University New Buildings, Edinburgh, 8; or to the Department of Infectious Diseases, The Brownlee Research Laboratory, Ruchill Hospital, Glasgow, N.W.

T. ANDERSON.

ALLERGY

Études Cliniques, Expérimentales et Thérapeutiques sur l'Allergie. Published under the direction of Professor Pasteur Vallery-Radot. (Pp. 242. 900 francs.) Paris: L'Expansion Scientifique Française. 1951.

This small paper-bound book consists of 29 articles, most of them short, which were presented recently before the French Allergy Society or at the first European Congress of Allergy held in Paris in 1950. The fact that the book is edited by Professor Vallery-Radot and Professor Tzanck indicates that the selection will be good. The subjects vary from the daily distribution of the mould flora of Paris and allergic cases of various types to experiments on allergy in animals. As was probably to be expected, the most interesting experimental reports are those of Halpern and his co-workers on the antihistamine drugs. They show that in the rabbit these drugs inhibit the Schwartzmann reaction and they tend to suppress local inflammatory reactions, thus allowing more rapid spread of infection in animals injected with *Salmonella typhi-murium*. A number of papers are on dermatitis due to various antibiotics and other drugs, and Professor Tzanck points out how much more often sensitization occurs when penicillin is used locally as a cream than as a solution. This book gives a fair indication of French thought on allergy.

C. J. C. BRITTON.

KEEPING UP TO DATE

Annual Review of Medicine. Volume 2. Editor, Windsor C. Cutting; Associate Editor, Henry W. Newman. (Pp. 486. \$6.) Stanford, California: Annual Reviews Inc. 1951.

Medicine of the Year. 1951 edition. Edited by John B. Youmans, M.D. (Pp. 298. £2.) Philadelphia and London: J. B. Lippincott Company. 1951.

Cornell Conferences on Therapy. Volume 4. Edited by Harry Gold, M.D., D. P. Barr, M.D., McKeen Cattell, M.D., Frank Glenn, M.D., Walter Modell, M.D., and George Reader, M.D. (Pp. 342. \$3.50, or £1 6s.) New York and London: The Macmillan Company. 1951.

In an age when most full-time workers in medical schools think themselves accursed if they have not succeeded in publishing some two or three papers a year, no matter how dull or mediocre, it becomes increasingly difficult for the average doctor to have even a nodding acquaintance with the vast literature which accumulates annually, still less to be able to say which paper is or is not worth while. It is scarcely surprising, therefore, that yearbooks of medicine and annual reviews of recent advances should become increasingly popular and increasingly useful. In such works a group of experts predigest the literature pertaining to their own subject, critically separate the good from the bad, and serve up the result in a concentrated, intelligible, and acceptable form.

Three books from America do this sort of thing very well but very differently. The *Annual Review of Medicine* contains a series of essays by experts in which recent advances in medicine only are broadly and critically surveyed. An extensive bibliography covering the references appears at the end of each chapter. Almost without exception the reviews are admirably done. They are clearly designed for those engaged in teaching or research whose knowledge of the subject under discussion is already well established. In *Medicine of the Year* the year's advances in all fields of medicine, including surgery and other specialties, are briefly reported in a more tabloid form. This is a general work of reference more useful for the general practitioner than for the specialist, though valuable for the latter too for information on subjects outside his own sphere.

The *Cornell Conferences on Therapy* were inaugurated in 1937 as a joint venture of the departments of medicine and pharmacology. To qualify for a conference a subject must be a problem in therapeutics on which widely divergent views may be held. They are introduced by a prepared talk from an appropriate member of the staff, and thereafter the discussion, no doubt carefully edited, is reproduced as an unrehearsed and extempore debate understandable to the general practitioner. The purpose is to stimulate interest in rational therapy and the method a report of a spontaneous, informal, and free discussion. It is all great fun and very easy to read as one's partisan interest is excited by this or that speaker in the debate. The course in pharmacology in most schools is isolated by some terms from that on clinical therapeutics, and to a considerable extent clinicians are apt to build the structure of therapeutic teaching with indifferent regard to its pharmacological basis. These conferences help to correct this tendency and to weave pharmacology and therapeutics into a single design. The conference is not a substitute for, but ancillary to, traditional forms of medical teaching and one which should be explored more fully in Britain.

THUS WE ARE MEN

The foundation of a lectureship at the Royal College of Physicians by Lady Langdon-Brown in memory of her husband, Sir Walter Langdon-Brown, ensures the recurring recollection of a remarkable man who was also a loyal and devoted Fellow of the College. The President and Censors, with fortunate prescience, appointed Dr. Geoffrey Evans, Langdon-Brown's pupil, colleague, and collaborator, to deliver the inaugural lecture. By a tragic circumstance Dr. Geoffrey Evans did not survive to deliver the lecture which he had prepared and which appears elsewhere in this issue, and it was read with sympathy and understanding on October 30, 1951, by the President of the College, Dr. Walter Russell Brain. This was, therefore, doubly a memorial occasion, and Geoffrey Evans, in paying this fine tribute to his friend, had written for himself a splendid epitaph.

The lecturer described the puritan home of Walter Langdon-Brown in Bedford, with its abiding influence on his personality, and then told of his delighted emergence into the undergraduate life of Cambridge. His work in the Cambridge school of physiology and his association with Michael Foster and Gaskell gave his mind a stimulus which remained to the end of his life. The quoted description of his excitement as he watched the development of the pituitary gland in serial sections of the hen's embryo authentically communicates the thrill of scientific observation.

A different discipline awaited him at St. Bartholomew's Hospital, and Geoffrey Evans sketched the hospital background at the end of the century with Samuel Gee, whose house-physician Langdon-Brown became, as the peerless bedside observer; Norman Moore, as the scholar physician; and Archibald Garrod as the first of the clinical scientists. Here Langdon-Brown himself learnt to observe the processes of disease, both in sick persons and in the post-mortem room—a long and fruitful apprenticeship, for he was 43 years of age before election to the staff of St. Bartholomew's Hospital. By that time he had already made a highly individual and important contribution to the medicine of his day. Almost alone among physicians in his knowledge of physiology, and

stimulated by a profound desire to get sick people well, he wrote his famous textbook *Physiological Principles in Treatment*. It was an inspiring book for his generation, and, although the available therapeutic resources look meagre enough as one reads the first edition to-day, yet it was the first published application of physiology to clinical medicine and therapeutics. Here Langdon-Brown was a pioneer who has had many distinguished successors, but as the man who designed and built the first bridge he deserves honoured remembrance.

His second great service to the medicine of his generation was another essay in bridge-building, and he was again impelled to it by the necessities of treatment—the continuing impulse to heal the sick. After the first world war he began to correlate the hypotheses of the new psychology, represented in the work of Freud, Jung, and Adler, with clinical medicine. The researches of Gaskell, Langley, and Anderson into the autonomic nervous system and the increasing knowledge of the function of the ductless glands were the basis of his Croonian Lectures in 1919, and in them he stated for the first time his conception that these were the pathways by which emotional disorders were translated into disturbances of somatic function. This hypothesis he was to elaborate and restate in numerous addresses in succeeding years. Geoffrey Evans quoted a passage from his inaugural address as Regius Professor of Physic in the University of Cambridge in 1932. "Designed for an intensive preparation for action or defence," he said, "the sympathetic response may be dissociated, perverted, or prolonged, with serious effects to the individual," and the lecturer adds the comment that this introduces the ideas of organ habit and functional disorder as the cause of change of structure. Here again, as a host of successors slowly establish the steps in the complicated pathways between emotional states and physical disease, we are reminded of the recognition due to pioneers.

Langdon-Brown's legacy to this generation is his insistence on the unity of human personality—body, mind, and spirit—all aspects of one reality. An impairment of function of any of these components will adversely affect the harmony of the whole organism, and nothing which relates to human personality can therefore be foreign to medicine. The development of these ideas will be found in his book *Thus We Are Men*, of which Geoffrey Evans said, "It is a wonderful book to read." "Thus we are men and we know not how: there is something in us that can be without us, and will be after us; though it is strange that it hath no history what it was before us."

INSURANCE AND PENSIONS

A pamphlet¹ published last week by two Conservative Members of Parliament speaks of a crisis in the social services—"a crisis all the more dangerous for being unrecognized." Is this an exaggeration? Certainly no hint of a crisis appears in the second report² of the Ministry of National Insurance, published a few weeks before Christmas. It and its predecessor show that the colossal task of organizing an insurance scheme with about half the population paying contributions, and with most of the others covered either as dependants under the scheme or by family allowances, has been successfully achieved. None of the forebodings that the scheme would be too unwieldy to administer and that it would be impracticable to enforce it have materialized. The standard of compliance, even among the self-employed and non-employed classes, has been remarkably good.

What, then, is the crisis that Mr. Macleod and Mr. Powell speak of? The report of the Ministry of National Insurance goes no farther than the end of 1950. In the spring of last year the Labour Government raised the rate of retirement pension for the older pensioners. This in itself was important, for it represented a deliberate rift in the principles of the Beveridge report, which argued that a person needed the same guaranteed minimum income when his earnings were stopped by, say, unemployment as when they were stopped by sickness or retirement. But the increase in retirement pensions also explains the "crisis" in the social services. They were increased because of the growing inadequacy of the old rate to cover the cost of subsistence. It was laid down in the Beveridge report that the insurance benefit, paid as of right, should be adequate to cover the cost of subsistence in all normal cases. For the abnormal case national assistance was to be there to supplement or replace the benefit, but its scope in the insurance scheme as a whole was to be strictly limited. The "crisis" has arisen because the number of people applying for assistance to supplement their benefits is growing steadily.

As it turned out, the basic benefit of 26s. a week (42s. for a married couple) was never really adequate for full subsistence including rent. It was 2s. higher than the Assistance Board's scale of relief; but the Board's rate was exclusive of rent, for which an additional allowance was made. Thus even as early as the end of 1949, 18 months after the insurance scheme had come into force, of those being paid retirement pensions, sickness benefit, widows' benefits,

and unemployment benefit, 18%, 11%, 25%, and 11% respectively were receiving supplementary assistance.

Later the scope of national assistance was widened further. In 1950 the rising cost of living forced the Assistance Board to revise its rates. As a result the assistance allowance, exclusive of rent, was raised to 26s. for a single person and 43s. 6d. for a married couple. This meant that more people became eligible for assistance payments, and the same rising cost of living that compelled the Board to put up its rates also compelled more people to seek its help. By the end of 1950, therefore, the proportion of households whose benefits were being supplemented by assistance had risen to 21%, 13%, 28%, and 18% respectively in the four categories mentioned above. Last year, when the retirement pension was raised for the older pensioners by 4s. a week for a single person and 8s. for a married couple, a similar increase was made in the Assistance Board's scales. These are now, therefore, like pensions, 50s. for a married couple; but again it should be emphasized that this figure is exclusive of rent. Taking an average figure for rent of 14s., Mr. Macleod and Mr. Powell thus calculate that the minimum income needed for subsistence by a married couple is 64s. a week, and they point out that the higher rate of retirement pension is consequently 14s. below subsistence and that the other insurance benefits are 22s. below.

The Government met the cost of increased retirement pensions, widowed mothers' allowances, and children's allowances payable to persons drawing benefits or pensions, not by increasing contributions, but by assuming a more realistic rate of unemployment. Because the rate was originally assumed to be 8% and in actual fact has been below 2% the insurance fund has been running a large surplus. Last year, therefore, the unemployment rate was assumed to be 1½% up to 1954, 2½% in 1954-5, and 4% thereafter. But, as the Government actuary pointed out, the assumption of a lower rate of unemployment only temporarily relieves the Exchequer of its liability under the National Insurance scheme. In the financial year 1952-3 the Exchequer will pay £37m. into the fund to enable income to cover expenditure. But by 1957-8 the sum will have risen to £150m., and by 1977-8 the Exchequer contribution will have grown to nearly £450m.—some £40m. more than was contemplated when the National Insurance Act was passed in 1946.

This heavy liability in the years to come is due to the ageing of the population and the consequent increase in the expenditure on retirement pensions. Thus, the postponement of retirement, which is regarded as usually being in the best interests of

¹ *The Social Services*.¹ Published by the Conservative Political Centre.
² Cmd. 8412, 1951, H.M.S.O., London.

elderly people themselves, becomes of national importance. Unfortunately it is still too early to say whether the increased rate of pension since 1946 has outweighed the incentive of a higher pension still if a person postpones retirement. The report of the Ministry of National Insurance provides some provisional information on the subject, but it is admitted to be inconclusive. Roughly the same proportion of elderly people continue at work after reaching pensionable age as before July, 1948. For men this proportion is about 60%, for women about 50%. The proportion, however, falls off in the succeeding months, and 18 months after reaching pensionable age only about 45% of men and 33% of women are still at work.

Last year's National Insurance Act provided an additional incentive for people to postpone retirement by increasing the sum added to their basic weekly pension for each year they continue at work from 2s. to 3s. It will be some time before the effects of this on retirement are made clear. All that can be said at present is that we are a long way from achieving what, in view of demographic trends, must eventually be the objective—a normal retiring age five years older than the present minimum. In one respect a mere maintenance of the *status quo* in retirement trends is disappointing, for the same inflationary conditions which have reduced the value of the basic pension and other insurance benefits ought to encourage people to postpone retirement and at the same time make it easier for them to do so. If elderly people do not or cannot continue working when unemployment is at the rate of 1½%, what prospect is there of their doing so when inflation subsides and unemployment rises to, perhaps, 3%, which would be less than the long-term rate assumed by the Government actuary?

In two years' time the National Insurance scheme will be reviewed and a report made to the Treasury on the adequacy of the contributions payable to support the benefits. The Government should take the opportunity of assessing the adequacy of the benefits to cover the cost of subsistence. If, as is probable, they are found to be grossly inadequate, two courses are possible. Benefits and contributions could be raised all round, as Mr. Macleod and Mr. Powell suggest. The necessary increase in contribution would, however, fall severely on the lowest-paid workers. The Government might well, therefore, consider abandoning the present system of flat-rate contributions and benefits and substituting the system in force in many other countries of contributions and benefits related to earnings. This system was rejected by Lord Beveridge mainly because the benefits of the lowest-

paid workers would be bound to be less than the cost of subsistence. But since the present system has failed to guarantee benefits adequate for subsistence the time has come to consider the whole matter afresh. What would be unjustified would be to let most benefits stay well below subsistence and give more favours to old-age pensioners. Lord Beveridge's warning is worth recalling: "It is dangerous to be in any way lavish to old age, until adequate provision has been assured for all other vital needs, such as the prevention of disease and the adequate nutrition of the young."

OSTEOARTHRITIS

Any systematic study of the nature of a disease process requires first of all a clear definition of its characteristic clinical and pathological features. Perhaps one of the most serious weaknesses in our understanding of the arthritides has been a lack of such a definition of the various types of arthritis. In recent times we have moved from the eighteenth century concept of "gouty rheumatism" through that of Charcot,¹ who classified most arthritis under the same heading of "arthritis deformans," to that of A. E. Garrod,² who was able to separate two groups, rheumatoid arthritis and osteoarthritis. The rheumatoid group may well conceal a variety of conditions, whose most important common factor is that their aetiology is unknown; it is not necessary to assume that it is always the same. It is to be hoped that the present intensive study of this disease will bear fruit, although it must be admitted that so far the use of cortisone and A.C.T.H. as research tools has told us little in this respect.

Osteoarthritis, or degenerative joint disease, presents a problem of equal magnitude, and, as Ryle³ wrote, "There is no disease of which a fuller, or additional, description does not remain to be written." Since osteoarthritis accounts for some 30-40% of all patients attending rheumatism or similar departments, it might seem a fruitful field for simple clinical study, and every practising doctor must meet almost daily the problem posed by a patient suffering from this condition, with its very wide variety of symptoms. These arise not only directly from the affected joints but also quite often from the very natural anxiety

induced by the fear of arthritis. Orthopaedic surgery and physical medicine have made great contributions towards solving the problems of treatment, but the mere elaboration of specialized techniques such as cup arthroplasty cannot contribute greatly to our knowledge of the fundamentals of the disease itself.

For these reasons a clearer definition of osteoarthritis was essential, and Drs. J. H. Kellgren and R. Moore on page 181 of this issue provide a very definite advance towards this goal. What they term "primary generalized osteoarthritis" is distinguished from degenerative joint disease caused by trauma resulting from occupational, postural, infective, neurological, or similar factors. They suggest that there is a definite pattern of joint involvement which includes the terminal interphalangeal joints (Heberden's nodes) and the first carpo-metacarpal joints, and often most of the other diarthrodial joints of the body. The symptoms may be acute in onset, with swelling and redness of the affected joints followed by a more chronic and less painful phase, with bony overgrowth. Such cases in their early acute periods are often misdiagnosed as gouty—not only, be it said, by the lay public. Kellgren and Moore's concept of this phase as it affects the interfacetal joints of the spine is particularly interesting. They distinguish carefully between the involvement of these joints and the osteophytosis of the vertebral bodies often found in degeneration of the intervertebral disk. Both conditions may thus give rise to a very similar clinical picture, but radiography should enable a distinction to be made. They thus revive the ideas introduced by Putti⁴, and utilized by Bankart,⁵ who advised excision of these joints for lumbar or sciatic pain. A study of similar changes occurring in the cervical spine would also be of great interest, since, as Brain, Knight, and Bull⁶ have pointed out, the changes around the intervertebral foraminae in this region may give rise to syndromes of pressure on nerve roots, accounting for some cases of so-called fibrositis and neuritis. It seems probable that many of these patients would be found, on careful examination, to be suffering from primary generalized osteoarthritis.

Two other findings should be noted. Kellgren and Moore found tendon nodules in the flexor tendons of the hands in a few cases; that this is a frequent finding in rheumatoid arthritis has already been shown by Kellgren and Ball,⁷ but it is clear that their presence does not necessarily mean that the patient has rheumatoid arthritis. Secondly, they found that the sedimentation rate may be abnormally high, and this is a reminder that a raised rate does not necessarily indicate a rheumatoid type of arthritis, for in one-third of their tested cases the reading was between 20

and 40 mm. in the first hour (Westergren). This should discourage the routine use of gold salts in cases with a polyarthritis simply because the E.S.R. is raised.

Many questions remain to be answered: the curious localization in the terminal joints of the hands—only rarely found in rheumatoid arthritis, although always present in true psoriatic arthritis—and the discrepancy between the authors' findings and Stecher's⁸ finding of a correlation between the menopause and the onset of Heberden's nodes. Both groups agree, however, that there is probably a genetic factor. Stecher and Karnosh⁹ found, too, that an intact nerve supply was necessary for the production of Heberden's nodes, and this requires explanation.

The problem of treatment remains. It is important to remember that most patients with generalized osteoarthritis fear that they have rheumatoid arthritis, and a confident diagnosis, with an explanation that this condition is different and has a reassuring prognosis, is often the most important step and may be the only treatment required. At least it may save the patient from the hazard of widespread dental extraction or some other witchhunt for focal sepsis, and even from the not inconsiderable risk of gold therapy. Whether or not cortisone or, as Hollander and his colleagues¹⁰ suggest, hydrocortisone (Compound F) will offer practical help when administered direct into the joint remains to be seen. During the acute phase this may represent a rational approach by reducing the inflammatory reaction, although one cannot be sure that this reaction is not of itself beneficial by imposing rest on the joint. Its removal is not necessarily therapeutic.

Perhaps the most important point emphasized by Kellgren and Moore is the necessity for a study of the pathology of generalized osteoarthritis in its earliest stages. If the tissue changes occurring at this stage can be clarified we shall have made a great advance in understanding. Their definition of the problem to be tackled represents the first step towards this end.

WHITHER INFLUENZA?

What is the future outlook in influenza? Where and when will it break out next? Faced with these questions, the epidemiologist would like to hide his ignorance of the inner mechanisms of global epidemiology in the retort ambiguous, the reply which gave the oracle at Delphi its reputation in the time of Hippocrates. With the isolation and serological characterization of the influenza viruses A and B, however, it has been possible to see some pattern in the epidemiology of influenza. Stuart-Harris¹ has drawn attention to the two-year periodicity of influenza A outbreaks in this

country. Since 1933, when the virus was first isolated, influenza virus A has been recovered every odd year until last year—with one exception, 1945. In view of this periodicity and the well-known tendency of outbreaks to occur in the winter-time, we may infer by simple extrapolation that the next outbreak of influenza A in this country will be in roughly one year's time. Influenza B outbreaks do not show the same clear periodicity, so that sporadic outbreaks of influenza B are possible at any time this winter; if they occur these are likely to be restricted and mild, however. Compared with influenza A, influenza B outbreaks have generally been very tame.

In a recent article in this *Journal* Isaacs and Andrewes² showed that the 1950-1 influenza epidemic in Europe had two sources. A small outbreak of influenza in Sweden during the summer of 1950 preceded by four to five months the epidemic in northern Europe. In the Mediterranean area the causative virus was traced back to the southern hemisphere, where outbreaks of influenza had occurred in the South African and Australian winter six months earlier. In each case the evidence for the spread of virus was provided by strains isolated by World Health Organization laboratories throughout the world and sent to the World Influenza Centre for typing. World Health Organization laboratories will be on the look-out for virus during the next eight months; in particular, a summer outbreak of influenza in Europe should provide a useful "herald patch." This attempt to anticipate influenza outbreaks will fit in well with the trial of influenza virus vaccines recently sponsored by the Medical Research Council and the Ministry of Health.

In the United States of America evidence of periodicity of influenza, which earlier paralleled the experiences in Europe, has not been at all clear in the last few years. Each winter has produced a rise in the numbers of influenza cases, but no sharp peaks in incidence comparable to our experience in Europe have been found. During the 1950-1 European epidemic virus A is known to have been widespread in the U.S., but no major outbreak of influenza occurred. In seeking an explanation of these recent differences between influenza in the two continents we may speculate on the possible epidemiological importance of national boundaries in Europe. Clearly epidemic influenza does not respect national boundaries, but a milder endemic influenza may well do so. With its extensive communications the United States may be an ideal place for the spread of influenza virus, under conditions which would be against a major outbreak but would favour a mild endemic infection producing immunity against a later epidemic. In Europe, on the other hand, minor outbreaks such as that in Sweden in the summer of 1950 might not spread widely in the absence of free communications with susceptible populations in surrounding countries. Presumably with the arrival of winter in 1950 the susceptibility of the population in Sweden and elsewhere was lowered, partly because of waning of specific immunity and partly through other (perhaps

climatic) causes, and this resulted in epidemic spread. If this is so, the epidemiologist may yet be able to provide an argument in favour of a United States of Europe.

THE SCHOOL MEDICAL SERVICE

In the financial year 1948-9 the cost of the school medical service was £9½m.—about £1m. less than the previous year because of the transfer of hospital charges to the National Health Service account. Other effects of the National Health Service on the school medical service are referred to in the report¹ of the Chief Medical Officer of the Ministry of Education for the years 1948 and 1949. On the debit side there has been a falling off in the work of dental inspection and treatment, owing to the greater financial attraction of dental practice in the National Health Service, and delay in the supply of spectacles. On the credit side is the building up of a specialist service, including paediatricians, psychiatrists, and orthopaedic and ophthalmic surgeons, from which schoolchildren especially will obtain great advantage. The danger that the family doctor may be left out of the arrangements being made to improve the school medical service has been recognized by the B.M.A., and certain recommendations² have been made and approved by both the Association and the Society of Medical Officers of Health. As Sir John Charles writes: "The problem of bringing about a closer liaison between the school health service and the family doctor can only be solved by consultation and discussion between the doctors concerned, and it must be met in various ways according to local circumstances and personalities of the people involved."

The report is similar in form to those of previous years, much of the space being given up to quotations from the annual reports of school medical officers all over the country. There is a particularly good chapter on "The Diabetic Child" which surveys the history of diabetes in children since the discovery of insulin and describes the work of diabetic hostels. England is the only country in the world to have set up residential homes for diabetic children who cannot be looked after by their own parents. It is a great disappointment that the number of children found verminous at school inspections is falling so slowly. In 1949 very nearly half a million children in England and Wales—8% of those on the school registers—were infested. In spite of the new insecticides this figure is very little less than those of the years immediately before the war. It is of course not fair to blame the schools for infestation: the figures quoted in this report are a serious reflection on the social services generally. Some might question whether the improvements in health and education during the past fifteen years can really be as great as supposed if just as many children are verminous to-day as in 1937. Certainly the time has come when local education, health, and sanitary authorities should combine to attack infestation at its source.

Sir John Charles concludes his first report as chief medical officer to the Ministry of Education with a well-

¹ *British Medical Journal*, 1945, 1, 209.

deserved tribute to his predecessor, Sir Wilson Jameson, whose period of office, from 1940 to 1950, "was an exceptionally trying and difficult one; thanks to his wise guidance it was also an exceptionally fruitful one."

XYLOCAINE

Xylocaine was synthesized in 1943 by Löfgren¹ and Lundquist² at the Organic Chemistry Institute of the University of Stockholm, and was tested clinically in the Anaesthetic Department of the Karolinska Hospital. In Britain a trial was conducted by Drs. D. Carnegie and A. J. Hewer in 1950,³ at the invitation of the Faculty of Anaesthetists of the Royal College of Surgeons. Xylocaine has the signal advantage of acting more rapidly than any other drug of this group, yet maintaining its effect for a long period. It differs chemically from procaine and most other local analgesics through being a basic anilide, which has the formula *o*-diethyl-amino-2.6-dimethylacetanilide. It is a relatively non-irritant substance, it is not decomposed by boiling or by changes in pH, and it has no vasodilator effect; it does not affect the conjunctival vessels, nor dilate the pupil, nor cause mistiness of the cornea. The toxicity of the drug has been investigated by several workers, notably Goldberg^{4,5} in Sweden and Hunter⁶ in this country, who seem agreed that a total dosage of 1 g. is within the limits of its safety. Although "reactions" to the drug have been described, and the effects of accidental subarachnoid injection,⁷ there has been only one death reported, so far only in the lay press.⁸

Xylocaine is prepared by the manufacturers as a solution, either alone or mixed with adrenaline in a concentration of 1:100,000 in 0.5% and 1% solutions, or of 1:80,000 in 2% solution; the toxicity of the preparation would be reduced without loss of its efficiency if the adrenaline were in a dilution of only 1:250,000 in both. Carnegie and Hewer found that 0.5% solution maintained analgesia for three hours when given alone, and for almost six hours when combined with 1:200,000 adrenaline. The drug is used in a strength of 0.5 or 1% with adrenaline for infiltration analgesia, and of 1% or 2% for nerve blocking, caudal analgesia, or epidural analgesia. A 2% hyperbaric solution has been prepared for spinal analgesia. Xylocaine also has a surface action, and its use in a 2% solution for bronchoscopy has been described,⁹ though it was not as satisfactory as 10% cocaine. The 4% solution appears to be an improvement, but only a few cases have been reported.⁹

It is the action of xylocaine in the epidural space that emphasizes most strongly its superiority to other local analgesics, and the improved results reported by Drs. Ablett, Dawkins, and Steel¹⁰ will be corroborated by other anaesthetists. The more certain effects of xylocaine in this site may lead to a revival of interest in epidural analgesia.

EPIDEMIOLOGY OF CEREBROSPINAL FEVER

The statistical study of meningococcal infections must be approached with caution. In the early days of notification of cerebrospinal fever in this country the number of deaths from the disease exceeded the number of notifications, which is a clear indication that notification was grossly defective at that time. Deductions made from the records of recent years must allow for such administrative changes as the introduction of correction of notifications in 1944 and the change in nomenclature from cerebrospinal fever to meningococcal infections in 1950. These difficulties are multiplied when attempts are made to compare the incidence of the disease in a large number of countries with differing administrative systems and wide variations in the efficiency of the medical services. Nevertheless the study of the occurrence of infectious diseases throughout the world has become indispensable for a full understanding of their epidemiology, and Freyche's¹ report to the World Health Organization on the prevalence of cerebrospinal fever since 1939 is of great interest.

For the last twenty to thirty years the disease has been more common in the regions situated to the south of the North African desert belt than in any other part of the world. In Nigeria in both 1949 and 1950, and in the Sudan during the first half of 1951, there were more cases of cerebrospinal fever than in the whole Continent of Europe in 1940, when exceptionally large numbers of cases were notified. Each country experiences, in addition to the seasonal rise and fall, a periodic recurrence of high incidence at intervals from eight to twelve years. It appears probable that the crowding and migration of population that occur during the military and industrial mobilization of wartime have played an important part in determining the timing and size of some of the periodic waves. In England and Wales and a number of European countries the heaviest incidence of recent years was in 1940-1. The corresponding epidemic years in the United States were 1943 and 1944. There was a return of high incidence in France in 1945 and in the Netherlands in 1946. The timing of seasonal variations in different countries in the Northern hemisphere is remarkably similar, the crest of the wave being in the months of February, March, and April, and the trough between June and November. This makes it difficult to believe that the fundamental cause of seasonal changes in incidence can lie in such environmental influences as sand winds or movements of population that may be peculiar to any one locality. Realizing the danger of estimating case fatality from the available statistics, Freyche uses the term "statistical mortality rate" to indicate the relation between deaths from the disease and notifications. It has been noted in the past that this rate varies inversely with the seasonal variations in incidence, and it is shown in this report that it also varies inversely with the cyclical variations in incidence, but the reasons for this are not clear. It may be that in epidemic times the number of milder cases notified may be greater than in periods of low incidence, but this is probably not the whole explanation of these variations.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

THE PROS AND CONS OF IMMUNIZATION—I

BY

ROBERT CRUICKSHANK, M.D., F.R.C.P., D.P.H.

Professor of Bacteriology, St. Mary's Hospital Medical School, London, W.2

The articles that have hitherto appeared in this series have dealt almost exclusively with the diagnosis and treatment of established clinical diseases and infections. My task is to discuss the specific measures which the family doctor may use or recommend for the *prevention* of infection, in particular the use of vaccines and antisera to protect against the more common fevers of childhood and adult life—for example, diphtheria, scarlet fever, measles, whooping-cough, influenza, tuberculosis, typhoid fever, and smallpox. When we consider preventive measures against infection, the unit is usually the whole family rather than any individual member of it. A schoolchild has a sore throat which may be diphtheria or the early stages of scarlet fever and the doctor must decide what he can do to protect the other members of the family. Or mother has an attack of diarrhoea which may be food-poisoning or bacillary dysentery or the beginning of paratyphoid fever, and again measures must be taken to prevent spread of the infection to the rest of the family. Or, again, the doctor may be asked about the possibility and advisability of protecting a young family against whooping-cough or measles or smallpox before there has been any exposure to the risk of infection.

The control or prevention of infection in a family group may be considered under three main heads: elimination of the reservoir of infection, blocking the spread of the infecting organism, and raising the resistance of the susceptibles. One or all of these measures may be applied according to the circumstances of the case. The reservoir may be eliminated by early recognition and isolation of the primary case in the family, or by active antibiotic therapy which quickly rids the tissues of the infecting germs; spread of the organism may be prevented in the case of intestinal infection by instruction about personal hygiene and avoidance of food handling; and resistance may be raised by the use of specific vaccines and antisera to give "immunity" to the susceptibles.

What Is Immunity?

The medical student often seems to have difficulty in grasping the principles of immunity. The accompanying diagrammatic schema is often used to illustrate the different ways by which resistance to infection may be acquired, and an understanding of these principles is essential for a rational use of the artificial means of protection.

**Naturally Acquired Immunity**

Apart from an inherent immunity, which may be due to a genetic resistance to particular diseases or to the protection afforded by healthy and intact tissues, the individual may acquire by natural means an immunity of varying duration to specific infections. Thus the infant seems to be immune to such infections as measles, diphtheria, scarlet fever, and chicken-pox for the first few months of life. The explanation of this immunity is that antibodies to these various infections have been "manufactured" by the mother and passed, via the placenta, into the blood of the infant. So long as the specific antibodies persist in sufficient concentration the infant is protected against the corresponding infection, but these antibodies have not been produced by the child's tissues, so that they gradually disappear and are not replaced by fresh antibodies. This is called passive immunity and obviously gives protection for only a short period of time—usually for three to six months. The duration of this passive immunity will have a direct relation to the concentration of antibody in the mother's blood, and if the mother has no antibody to any particular pathogen, as often happens with whooping-cough and sometimes with diphtheria, the infant will be susceptible from birth to these infections.

When, on the other hand, a child develops an attack of measles at the age of 3 or 4 years he (or she) manufactures antibodies to the measles virus and is, as a result, resistant to further attack. This is an example of active immunity, which lasts for a much longer period than does passive immunity, although there are notable exceptions, like influenza and the common cold, pneumonia, and streptococcal infections. Here the lack of persistent immunity may be due to the superficial nature of the infection, as in the common cold and possibly influenza, so that the antibody factories throughout the body are not stimulated into activity; or it may be due, as in the case of pneumonia and streptococcal tonsillitis, to fresh attacks with new and different serological types of the pneumococcus or streptococcus against which the body has not acquired immunity. A further point about naturally acquired active immunity is that many of us become resistant to infections like scarlet fever and diphtheria as a result of repeated subclinical infection. Consequently the past history alone does not tell us whether an individual is or is not susceptible to these infectious diseases, but certain skin reactions, like the Dick and Schick tests, may give us the answer.

Artificial Immunization

If immunity is to be induced artificially the two main procedures are again passive protection and active immunization by agents deliberately introduced into the tissues; there is, in addition, the procedure of inducing a modified infection. Passive immunity is obtained by

VITAMIN C

NO TABLET CRUSHING
NO RESIDUE IN BOTTLE
CONTROLLED DROP DOSAGE

Cecon greatly simplifies the administration of ascorbic acid to children. All a mother has to do is to drop Cecon into the milk, cereal or other food — and mix it. Taken in this manner, it cannot be detected and is, therefore, especially suitable for supplementing the diets of infants and small children. • Accuracy in dosage is obtained by the dropper which is supplied with every bottle of Cecon, and you need only prescribe the number of drops that your patient is to receive. • Cecon does not curdle milk, does not oxidise or settle out, does not become gummy or sticky in the bottle or dropper, and does not require refrigeration. During use it can be kept on the pantry shelf without change in potency. • Cecon is especially suitable for infants, but it may also be prescribed for older children and adults. Supplied in 10 cc. bottle with a dropper.

(Abbott's Solution of Ascorbic Acid 10% w/v in Propylene Glycol)

ABBOTT LABORATORIES LIMITED, PERIVALE, GREENFORD, MIDDLESEX

Trufood or some other milk food— what's the difference?

Humanised Trufood is different because it is not just "another dried cow's milk". Cow's milk is, of course, our raw material. But the resemblance between Trufood and other dried milk foods ends there. The process of its manufacture makes Trufood a food specifically adapted to the nutritional needs of the infant who must be artificially fed. Because of this we sincerely believe that Trufood is the most satisfactory alternative for the baby who cannot have breast milk.

TRUFOOD

If you would like to know more about Trufood—how it is made, and why we think that it is the most satisfactory substitute for breast milk—write to the Trufood Professional Information Service, Green Bank, London, E.1. This service has been formed specially to answer questions from the medical and nursing professions, about infant foods.

the injection of either an antiserum prepared artificially in the horse or other animal against the infecting micro-organism or its active exotoxin, or the serum of a patient who has already had the disease. This antiserum confers an immediate specific resistance which lasts only until it is all excreted, usually in a matter of two to three weeks, depending on the dose of serum and the concentration of antibody. For example, tetanus antitoxin is given to an injured person to protect him against the risk of tetanus while his wound is being treated surgically, and if the injury is a severe one the dose of antitoxin may be repeated weekly for several weeks.

Active immunity is induced artificially by the injection of an antigen in the form of vaccine containing the intact micro-organism or virus in a modified form—for example, typhoid or yellow fever vaccine—or as toxoid, which is the exotoxin of the organism rendered non-poisonous by treatment with formalin—for example, diphtheria toxoid. Two or more injections of the antigen are usually needed to induce a sufficient degree of immunity, since the first injection (primary stimulus) does not evoke much antibody but prepares the antibody factories for a more active response to further injection (secondary stimulus). The immunity takes some weeks to develop, but persists for a much longer period—several months to several years—than that induced by the injection of an antiserum. As it wanes it can be quickly raised again by a small “booster” dose of the antigen. It is, however, important to warn the inoculated individual or his relatives that no form of artificial immunization, with the possible exception of yellow fever vaccine, will ensure complete protection against any particular infectious disease.

Active immunity may also be obtained by deliberately inducing a modified attack—for example, vaccination with vaccine lymph produces the disease vaccinia which gives protection against the more serious infection smallpox; or injection of convalescent measles serum in a child who has been exposed to infection may result in a mild attack of the disease which gives the child an active immunity without the upset associated with the unmodified attack.

The Risks of Reactions

Any form of immunization should, before it is recommended for general use, satisfy at least three criteria: it must be safe, it must be practicable, and it must be effective. Under the Therapeutic Substances Act all biological preparations issued for distribution must conform to certain requirements and must satisfy tests of sterility, potency, and absence of toxicity. These tests therefore ensure a high degree of safety in the use of sera and vaccines. However, reactions to the injection of these substances do sometimes occur and the practitioner must be aware of the risks.

The Syringe and Needle

It is, in the first place, essential that the syringe and needle used for giving an injection should be sterile. Boiling for five minutes in a saucepan immediately before use is the safest procedure. Ideally, the syringe and needle should be boiled between each injection, but if the doctor is giving a number of injections of the same material in a household he may adopt the method recently recommended by Fleming and Ogilvie.* Just enough material for one injection is taken into the

syringe. After the injection, with the plunger kept firmly home against the end of the barrel, the needle is withdrawn and, while still attached to the nozzle of the syringe, is immersed in boiling water for 10 seconds. This procedure sterilizes the needle. The syringe has not been contaminated and the doctor can proceed with the next injection without further sterilization.

If rubber-capped bottles are being used the top should be cleaned with spirit, and then with tincture of iodine, or the bottle may be covered with a metal cap on the under surface of which is a pad soaked in disinfectant. For injection of vaccines and toxoids a hypodermic needle of size 12–16 with a long bevel point should be used. For antisera a serum needle size 1 is best. It is most important that the needle should be sharp, and before the injection the point should be inspected to see that it is not turned. Needles of too fine a bore should not be used, as they may bend or break during the injection.

Reactions to Vaccines

Injections of vaccines and toxoids are best given in the deep subcutaneous tissues—for example, in the upper arm near the insertion of the deltoid or in the middle of the outer aspect of the thigh. The skin is sterilized, preferably with 2% iodine or 70–75% alcohol, a fold of the skin is picked up between thumb and first finger, and the needle is then injected with a stabbing movement into the fold of the skin. Reactions of two kinds may occur—local or systemic. The local reaction, coming on in two to three hours, is due to the irritation produced by the foreign material, and is more often present after the injection of bacterial vaccine, particularly T.A.B. vaccine, than after toxoid. If the toxoid contains alum a fibrous nodule and occasionally a sterile abscess or cyst may form, and therefore the material should not be injected too superficially. Constitutional symptoms such as headache, malaise, nausea, and pyrexia are again more common after an injection of bacterial vaccine like T.A.B. and may last for one to two days. Prophylactics which may be expected to produce some constitutional upset should be given in the late afternoon, and the individual should be advised to take 5–10 gr. (0.32–0.65 g.) of aspirin before going to bed. Very rarely a condition of protein shock with rigor and high temperature may come on within half to one hour after an injection if some of the material has accidentally entered a vein.

A more serious complication of prophylactic injections has recently come to light in the form of post-inoculation poliomyelitis. Certain cases of poliomyelitis have developed within a month of the injection of prophylactics like A.P.T. (alum-precipitated toxoid), or combined diphtheria toxoid and pertussis vaccine, and the paralysis has usually been in the inoculated limb, mostly an arm. Statistical analyses have indicated that this association is more than a chance coincidence, and the most likely explanation is that the injection has activated a pre-existing latent infection with the poliomyelitis virus and localized it, perhaps because of the tissue trauma, in the motor nerve cells associated with the affected muscles. This complication may best be avoided by giving the injection subcutaneously rather than intramuscularly, by using prophylactics that are least likely to produce local tissue damage—for example, formol toxoid rather than A.P.T.—and by suspending inoculation of children in the susceptible age group—that is, over 1 year of age—in an area where poliomyelitis is known to be occurring at the time.

**British Medical Journal*, 1951, 1, 543.

Reactions to Antisera

The injection of antiserum derived from horse or other animal may cause either a sudden anaphylactic shock or a delayed serum sickness. Anaphylaxis is extremely rare in the human subject, and in its fatal form is most likely to occur in persons who have some inborn or acquired predisposition to allergic disorders like asthma, eczema, or urticaria. Before giving an injection of antiserum, therefore, the doctor should inquire about a personal history of asthma or hay-fever, particularly from contact with horses, or any family or personal history of allergic disorders. If in doubt an intradermal injection of 0.1 ml. of the serum diluted 1 : 100 should be given; this will produce a local wheal and erythema reaction in a sensitized person, who may then be partially and temporarily desensitized by repeated small injections of the serum.

Serum sickness, developing seven to ten days after the injection of the antiserum, and characterized by an urticarial rash, joint pains, and fever, was common when crude unconcentrated antitoxin was used in large doses. The introduction of concentrated antisera, and later of enzyme-digested "refined" antitoxin given in small doses, has reduced the incidence of serum sickness to less than 3%, so that this complication is now a rare hazard. Antihistaminic preparations locally or systemically will usually give relief. The patient who has had an injection of foreign protein such as horse serum within the past three to six months may develop an acute anaphylactoid reaction, with dyspnoea, pains in the chest, and oedema of the face, within a few hours of receiving a second injection. This type of reaction, while alarming, can usually be prevented or controlled by an injection of 1 ml. of 1 : 1,000 adrenaline. With convalescent human serum, particularly if it is prepared from a pool of donors, there is the small risk of homologous serum jaundice coming on two to three months after the injection. This risk can be largely prevented by "sterilizing" the serum with ultra-violet light and is practically non-existent with concentrated gamma globulin. Injections of whole blood should not be given, because they may induce the formation of rhesus antibodies.

Prevention versus Cure

It is sometimes said in these chemotherapeutic days that there is no advantage in trying to prevent infections that can be easily cured with modern antibiotics. Why, for example, subject people to the inconvenience of T.A.B. inoculations when typhoid fever can be treated effectively with chloramphenicol? A similar argument was used many years ago for diphtheria, when it was hoped that the use of a specific antitoxin would bring this infection under control, but, in spite of all efforts at earlier diagnosis and better therapy, some 60,000 cases of diphtheria, and around 3,000 deaths, continued to occur every year in England and Wales until large-scale immunization was introduced in 1940. As a result there were 957 notified cases of diphtheria and only 49 deaths in 1950, while the saving in hospital beds and in expert medical and nursing care has greatly reduced the total expenditure on this once dreaded infection. Thus it has been calculated that the dramatic reduction in the incidence of diphtheria has meant a saving to Scotland of something over £300,000 a year, while reduction from nearly 10,000 to a few hundred cases annually represents a saving of about 750 hospital beds on every day of the year and an annual saving of some 250 full-time

nurses and a proportionate number of doctors, hospital domestics, etc.

Furthermore, in diseases with insidious onset, such as typhoid fever and whooping-cough, the damage to the patient and his contacts has already occurred before effective treatment can be given. There is little doubt, therefore, that where specific prophylaxis is safe, practicable, and effective prevention is always better than cure. On the other hand, certain infectious diseases, such as lobar pneumonia, cerebrospinal meningitis, and typhoid fever, tend to occur rather sporadically in civilian practice and to affect only a small proportion of the population at risk, so that even if effective prophylactics were available large-scale indiscriminate immunization would not be thought profitable. Where, in special circumstances, the risk is considerable, and the prophylactic effective, as happens with typhoid fever among troops on active or foreign service, then obviously prophylaxis is again better than cure.

The specific measures that may be used to protect against particular diseases, and the indications for their use, will be discussed in the next article in this series.

THE INCIDENCE AND PROGNOSIS OF CEREBRAL PALSY

AN INTERIM REPORT

BY

IRENE M. HOLORAN, M.B., Ch.B., D.C.H.

Assistant School Medical Officer, Leeds

In Leeds County Borough a special day school with 140 places caters for all types of physical handicaps other than defects of sight and hearing. The more severely handicapped from cerebral palsy attend here, and in addition it is expected that a residential school for the younger cerebral palsy children will be opened in 1952.

Incidence

The survey of cerebral palsy occurring between the ages of 3 and 16 in Leeds was begun in 1947. During that year an assessment was made of all the children on the school roll known to be suffering from cerebral palsy, including those attending ordinary schools as well as special schools. It did not include children already notified to the mental health authority as ineducable and many children under 5. All the children have been examined by Mr. J. M. P. Clark, orthopaedic consultant to the local authority, and by me. Those attending the day school for the physically handicapped have also been examined by Dr. J. D. Pickup, late lecturer in paediatrics, Leeds University.

The first survey in Leeds as published in the Annual Report of the School Medical Officer for 1947 mentioned 97 children, and the annual report for 1949 shows 136. The present figure is 141. The reasons for the rise in figures for Leeds appear to be as follows:

1. The knowledge that some plans were in preparation for the young cerebral-palsied resulted in more young children being referred from the paediatric and orthopaedic departments of the local hospitals. The latest ascertainment figure includes 19 children between 3 and 5 years of age and five not included in the survey who are under 3 years old. Since the school population includes very few children under 5 at the present time, a more

accurate incidence in proportion to the school population might be obtained by omitting the 19 children aged 3 to 5. Again, since the school population includes a minority of children over the age of 15 it would be more accurate to exclude those aged 15 to 16. The number would thus be reduced to 107—that is, 1.6 per 1,000 of the school population, reckoning the school population of Leeds as 66,548. The known figure for the whole country is 1 to 2 per 1,000. Sheffield reports 1.9, and Birmingham 1 per 1,000 (*British Medical Journal*, 1950, 2, 1051) of the school population and later 0.9 per 1,000 (Asher and Schonell, 1950). The American figure is 4 to 5 per 1,000 (Phelps, 1941).

2. Another factor causing the rise is the inclusion of a number of mildly afflicted children, hitherto undiagnosed. These came to light owing to the generally increased interest in cerebral palsy amongst all members of the school health service, who referred for investigation an increasing number of children showing slight symptoms. The reason given to parents and teachers for a child's clumsiness, slovenly speech, and relative dullness compared with his siblings produces a much more sympathetic attitude, and an acceptance of the child's disability as such rather than as original sin. In this more favourable atmosphere the child often improves considerably.

3. The third factor that produces a rise in the numbers recorded between 1947 and now is that the present list includes 14 children notified as ineducable during that time. Eight were notified before starting school; the other six proved ineducable after a trial in school or incapable of further education after profiting for a time.

Value of a Pre-school Clinic

A pre-school clinic has been started for children under 5 years, and for those over 5 years who are too handicapped to benefit yet from a day special school. The children attend twice weekly for physiotherapy and speech therapy (if required), and are provided with transport if necessary. While far from ideal in frequency of treatment owing to the difficulty in obtaining sufficient attendance of skilled personnel, the clinic has proved of great value.

The children make progress, and parents are taught how to help the children at home and are encouraged by meeting other parents in the waiting-room with similar problems. Much useful information is exchanged and a happy atmosphere prevails. Perhaps the greatest value of the pre-school clinic is that the observations of skilled staff over an appreciable period are available for the difficult task of assessing the educability of severely handicapped children. In the light of reports from the speech therapist and the physiotherapist, along with a Terman-Merrill assessment of intelligence where possible, the medical staff responsible can send the child to school with some confidence that he will profit there both educationally and physically, or they may decide that there is evidence from prolonged observation that the child is ineducable—a decision that could not possibly be arrived at from one or two interviews only. Before the pre-school clinic was started valuable places in the day special school had to be devoted to giving these children a trial. This wastage is now largely avoided.

Type of School Suited to Children with Cerebral Palsy

Unlike the voluntary schools, whose screening personnel merely accept or reject a child as suitable or otherwise for that particular class of school, a local authority has to make a recommendation regarding the

place into which the child will fit. Table I shows how 141 children aged 3 to 16 with cerebral palsy have been placed.

Thus about half the children with cerebral palsy occupied a place in a school for the physically handicapped for part if not all of their school life.

TABLE I.—The Placing of 141 Children Having Cerebral Palsy

Secondary grammar school	2
Secondary commercial school after day school for the physically handicapped	1
Primary or secondary modern school	37
Primary or secondary modern school, after day school for the physically handicapped	17
Private school after day school for the physically handicapped	2
Day school for the partially sighted, after day school for the physically handicapped	1
Day school for the educationally subnormal, after primary school	5
Day school for the educationally subnormal, after day school for the physically handicapped	10
Private school instead of school for the educationally subnormal	1
Residential school for the physically handicapped	1
Day school for the physically handicapped	21
Home teacher advised	2
Awaiting school for the physically handicapped (all under 6 years old)	14
Under 5 years old, and probably fit for primary school at 5	4
Under 6 years old and probably ineducable	6
Notified to the Mental Health Authority as ineducable	17

Distribution of Intelligence

Table II shows the distribution of innate intelligence amongst the group. The test used was the Terman-Merrill revision of the Stanford-Binet tests, and all the tests were applied by me.

While realizing the difficulties of obtaining a valid intelligence quotient from children suffering from severe cerebral palsy, the findings given below may be of some value, particularly as more than half the children are not so handicapped as to require provision for special physical education.

TABLE II.—Distribution of Intelligence in the Cerebral-palsy Group (Terman-Merrill I.Q.)

Less than 35	6 (4.5%)	85-94	30 (22.6%)
35-44	8 (6.0%)	95-104	15 (11.3%)
45-54	9 (6.8%)	105-114	5 (3.8%)
55-64	15 (11.3%)	115-124	3 (2.2%)
65-74	20 (15.0%)	Over 124	Nil
75-84	22 (16.5%)		
Completed			133
Gone to work at 15 and change of address untraced			1
Probably ineducable; no figure possible as yet (under 6 years)			4
Probably educable; no figure possible as yet (under 4 years)			2
Probably educable; no figure possible as yet (under 6 years)			1
Total			141

The difference in the distribution of intelligence between the cerebral-palsied group and a normal group is striking and disagrees markedly with the American estimate (Phelps, 1938) that 70% of children suffering from cerebral palsy have intelligence spread over the same distribution as the general public and that many of these children have a high-grade intelligence when their disability will allow them to use it.

The graph on the next page shows the normal distribution of intelligence compared with the distribution in 133 children suffering from cerebral palsy. It appears that far fewer children fit for an academic or technical type of education will be found in a group of children with cerebral palsy than in a normal group.

The highest proportion of children with cerebral palsy come within the dull group. Those of normal and super-normal intelligence as a whole form only 24.8% as

Graph showing normal distribution of intelligence (Terman-Merrill I.Q., —) compared with distribution of intelligence in 133 children suffering from cerebral palsy (Terman-Merrill I.Q., - - - - -).

against 75% in the normal population. Conversely, 33.3% have intelligence quotients under 70, whilst only 3% of the ordinary population come into this category.

This distribution of intelligence agrees closely with the findings of Asher and Schonell in their summary of 354 cerebral-palsy children in Birmingham and district.

TABLE III.—Distribution of 141 Estimated Intelligence Quotients of Cerebral-palsy Groups Compared with Asher and Schonell's Estimation and With the Normal Child Population

I.Q. Level	Present Group		% Asher and Schonell	% Normal Population	Usual Nomenclature	Suitable Provision

The Ineducable Children

Parents may apply for the admission to a residential colony of an ineducable child whom they are unable to care for at home. In addition to a residential colony, Leeds is fortunate in possessing two day-occupation centres under the care of the mental health authority. Most children who are notified as ineducable have the opportunity of attending a day-occupation centre. Transport is provided, and quite severely handicapped children are cared for. The regular regime on graded nursery-class lines for all ages proves beneficial in many ways. The children are happy to be with others and become more independent and more socially acceptable. Parents agree to a child's notification less reluctantly when some training is still provided for the child and when some solution is offered of the domestic problem often created by having a severely handicapped child in the home all day.

When a child appears likely to be ineducable it is advisable to tell the parents early that there are doubts about how much progress the child will make. If the parents can be helped to accept the truth about the child's disabilities, and their confidence in the doctor can be kept, much unhappiness will be avoided. They will not suffer from feelings of resentment that "Authority" has not given their child a fair chance, nor from disappointment as a result of seeking a multitude of opinions or quack remedies. If difficulty arises a further six-months delay may convince those hitherto unconvinced when the greater progress of other children in the pre-school clinic is seen. A visit to an occupation centre will often clinch matters. It should always be pointed out that should the child make unexpected progress it is possible to cancel a notification.

Employability

The placing of cerebral-palsied children in suitable employment when they leave school presents its own difficulties even in a city, such as Leeds, whose industries are avid for juvenile labour. When one or both hands are affected; when speech may still be slightly abnormal, when the intelligence is too poor to allow of clerical work, when there is accompanying epilepsy, or when some of the emotional instability so typical of cerebral palsy may still remain, the problem is a difficult one. A patient with severely crippled legs, or an educationally subnormal child with strong limbs, is much easier to place than one with the mixture of disabilities apt to be found in the spastic child even though each disability may not be severe in itself.

Of 17 educable children who have left school and are over 16 years old, one is having further training in a private "commercial" school, one is working satisfactorily since leaving school, two have just been satisfactorily placed, two are working for relatives, three have had several changes of job and are difficult to place satisfactorily, four are at long-stay training establishments—e.g., Alton, Oswestry—with a view to home industry such as shoe-repairing, and four are at home unable to work at all.

Of eight children aged 15 leaving school at that age, and therefore all comparatively mildly handicapped and having attended ordinary school, four are working satisfactorily, one has just been satisfactorily placed, one has had several changes of job already, and two have changed addresses and cannot be traced.

From these small groups of children who have left school it would appear that any complete schemes for dealing with cerebral palsy must include sheltered workshops and home industries.

Conclusions

The incidence of cerebral palsy in Leeds children aged 5 to 15 is 1.6 per 1,000 of the school population.

A pre-school clinic is a vital part of any scheme for the treatment and education of children suffering from cerebral palsy.

The condition of half the children has required that part or all of their school life be spent in a special school for the physically handicapped.

Occupation centres do valuable work in rendering the ineducable children more socially acceptable.

The distribution of intelligence is lower than in a similar group of normal children.

SOLUBILITY 98%

The solubility curve of Urolucosil* reaches a maximum of 98% at pH 7. The product is consequently ideal for treatment of *B. coli* infections of the urinary tract. In such conditions high urinary concentration is essential: during Urolucosil therapy, therefore, only the minimum amount of fluid should be taken. This would appear to be directly contrary to normal practice with sulphonamides, but the high solubility combined with a low percentage of acetyl derivatives in Urolucosil ensures that a dose so small as 0.1G. Urolucosil four-hourly will give a urinary concentration as high as 20 mg. per 100 c.c. — a concentration more than adequate for sterilization of the urine. The smallness of the dose and the low acetylation rate combine with the high solubility to make the risk of side-effects negligible with Urolucosil.

Each tablet contains 0.1G. 2-sulphanilamido-5-methyl-1-thio-3 : 4-diazole.

William R WARNER and Co., Ltd., Power Road, London W. 4.

Aqueous Suspensions of B.D.H. Sex Hormones FOR QUICKER ACTION AND PROLONGED EFFECT

These new B.D.H. Products consist of suspensions of oestradiol monobenzoate, progesterone and testosterone propionate respectively in saturated aqueous solutions of the hormone. Aqueous suspensions have the following advantages:

1. Prompter action than that obtained with oily solutions.
2. Duration of effect is somewhat longer than with comparable doses of oily solutions.
3. Finer needle can be used.
4. Injection is painless.
5. Syringe need not be thoroughly dried before use.
6. Absence of oil makes syringe easy to clean.
7. Dosage is the same as for oily solutions.

'OESTROFORM' AQUEOUS (Estradiol Monobenzoate B.P. in aqueous suspension (Ampoules containing 1, 2 and 5 mg. in boxes of 6 ampoules)

'LUTOFORM' Progesterone B.P. in aqueous suspension (Ampoules containing 5, 10 and 25 mg. in boxes of 6 ampoules)

'TESTAFORM' Testosterone Propionate B.P. in aqueous suspension (Ampoules containing 5, 10 and 25 mg. in boxes of 6 ampoules, and 50 mg. in boxes of 3 ampoules)

Descriptive literature and specimen packings are available on request

THE BRITISH DRUG HOUSES LTD. (Medical Dept.) LONDON N.1

Shor/E/204

The outlook need not be clouded...

... by the shadowy fear of the menopause and its associated vasomotor and psychic disturbances.

Euvalerol M, the ideal sedative in menopausal conditions, ensures that the difficult years may be contemplated with equanimity and passed through with ease.

Symptoms of apprehension, flushing, irritability and depression that darken the outlook of the woman at the menopause are alleviated, and the emotional balance restored, by the administration of Euvalerol M.

Euvalerol M contains an odourless preparation of valerian with $\frac{1}{4}$ grain (16 mg.) phenobarbitone and 0.1 mg. stilboestrol in each fluid drachm.

EUVALEROL M

In bottles of 4 and 8 fluid ounces.

Literature on application.

The placing of these children in suitable work presents considerable difficulty. Home industries and sheltered workshops are needed for a complete scheme.

Thanks are due to Mr. J. M. P. Clark for much helpful criticism and advice, and to the Leeds education authority and to Dr. I. G. Davies, school medical officer and medical officer of health, for permission to publish this report.

Preparations and Appliances

A LARYNGOSCOPE BLADE FOR INFANTS

Dr. R. BRYCE-SMITH, first assistant, Nuffield Department of Anaesthetics, University of Oxford, writes: Difficulty is often experienced in exposing the larynx of a newborn baby by those who are not adept, and for this reason intubation in asphyxia neonatorum is rarely practised by the obstetrician or general practitioner. A laryngoscope blade has been designed to give a satisfactory view of the cords whether it is introduced anterior or posterior to the epiglottis, or with the head either extended or flexed. Most other blades for children are not intended for the newborn, and in my hands have not given completely satisfactory results.

The blade has a three-quarter-circle cross-section for the greater part of its length (7.5 cm.), and tapers from a maximum width of 1.8 cm. at the proximal end to 1 cm. at the

"a" represents light carrier.

tip. The distal 2.5 cm. is curved slightly, and although it has an open section it is guarded on the left side to retract the tongue. There is sufficient overhang on the open side to prevent the lips from obscuring the view. The broad flat lower surface does not damage the gums. Though intended primarily for newborn babies, the blade is made long enough for use on children up to 3 years of age. Over a period of six months it has given satisfactory results in this range and has been of value in children with cleft-lips and cleft-palate.

The bulb is mounted on a detachable Melbourne-type light carrier for ease of sterilization and replacement. The blade fits any Longworth laryngoscope handle.

I am indebted to Mr. Richard Salt, of the Nuffield Department of Anaesthetics, for his help in developing and designing this blade, which may be obtained from the Longworth Scientific Instrument Company, Thames Street, Abingdon.

Reports of Societies

CONSERVATIVE TREATMENT OF THE DISK SYNDROME

At a meeting of the Section of Physical Medicine of the Royal Society of Medicine, held at 1, Wimpole Street, W.1, on January 9, there was a discussion on "The Conservative Treatment of the Disk Syndrome." Dr. H. F. TURNER, president of the Section, was in the chair.

Dr. E. J. CRISP, who opened, said that the lumbar disk lesion—a lesion which knew no age limit—was the commonest cause not only of sciatica but of acute and chronic low back pain. Though the disk was a comparatively avascular structure, he believed that repair of annular tears could take place, though slowly, by vascularization from the adjacent spongiosa or from extradural vessels.

Terms such as "slipped" or "prolapsed" disk were most misleading: disks could not slip and seldom actually prolapsed. The usual lesion was an incomplete annular tear resulting in a postero-lateral bulge of greater or lesser degree. Some idea of the extent of the lesion might be deduced from the clinical picture. With a small annular tear, especially if accompanied by injury to the ligamentum flavum, the lumbar spine was usually held in tight lordosis by protective muscle spasm, little or no forward flexion being possible. Conversely, if there was a large posterior protrusion the lumbar curve would be reversed, and though forward flexion might be possible the patient would be unable to stand upright.

Conservative Measures

The object of treatment was to allow any protrusion to reduce, inflammatory reaction to subside, and repair to take place. Possible methods of treatment included bed rest, plaster jacket, traction, manipulation, epidural injection, physiotherapy, and spinal brace, etc. Cases of average severity usually did well with complete bed rest for three or more weeks. But quite a number failed to respond, usually because complete rest was impracticable. The plaster jacket was a much more effective method of treatment: it splinted the back, allowed repair to take place, and was good for the morale, as the patient could be ambulatory. It was essential to wear the jacket for two to three months, and a spinal brace for a similar period subsequently.

The case with the reversed lumbar curve could often be relieved dramatically by sustained traction on the traction table, the protrusion reducing and the lumbar spine regaining its normal shape; after that a plaster jacket was applied. If traction was not available the protrusion reduced equally well but more slowly in a plaster jacket, though it was necessary to remove the jacket when reduction had occurred and apply a new one with the lumbar spine in the corrected position. Manipulation was contraindicated in the acute stage, but was often effective for the chronic case or for the relief of residual pain following immobilization in plaster. Sustained traction might be equally effective for this type of case. Short-wave therapy for the relief of pain and inflammation, and hyperextension exercises to strengthen the sacrospinalis group of muscles, were rational and valuable physiotherapeutic measures, but they should not be used to the exclusion of rest, but rather as supplementary measures in the resistant case. Exercises which flexed the lumbar spine should be avoided, and lumbar flexion allowed to return spontaneously. The vast majority of patients with lumbar disk lesions could be relieved by conservative methods if sufficient attention were paid to details.

Cervical Disk Protrusions

Dr. M. KREMER considered that the commonest cause of brachial neuralgia was probably a lesion in relationship with the shoulder-joint. Where a cervical disk protrusion

was the cause some neurogenic symptom or sign would be present. The pain in the early stages was caused by ligamentous lesions and occasioned by spasm of the cervical muscles. Later, when the protruded fragments of disk impinged upon one of the cervical nerves, radicular pain appeared—both a distally shooting superficial pain and a more proximal aching myotonic pain in the muscles supplied by the affected segmental nerve. Paraesthesiae in the peripheral distribution of the affected nerve were common. Examination would disclose hypotonia, wasting, and eventually weakness of the muscles supplied by the involved nerve, and diminution of the tendon reflexes was common. Objective sensory disturbance was, however, rare. Radiological examination of the cervical spine in such cases would often show narrowing of disk spaces and osteoarthritic change, but the significance of these x-ray changes was far from clear; since identical changes might be present in the absence of symptoms. In treatment rest was all-important. Ideally this should be in bed in a half-sitting position, the head supported on pillows with a sandbag on each side to prevent lateral movement, and a pillow beneath the knees to facilitate the maintenance of the sitting position. The weight of the arms should be carried on pillows. Adequate doses of analgesic drugs were required, morphine being given in the early stages if necessary. Later a mixture containing two or three compound codeine tablets with half a grain (32 mg.) of codeine phosphate added was useful. This was given four-hourly by day, and at night 15 to 20 minims (0.9 to 1.2 ml.) of "nepen-the" was added. Basal sedation with amylobarbitone, 1 gr., was also useful. Heat applied to the shoulder by means of an electric pad might be helpful, but other forms of physiotherapy were contraindicated.

If pain continued for two to three weeks in spite of this regime traction was applied to the neck by means of a Crile halter to which was attached a weight of 6 to 14 lb. (2.72 to 6.35 kg.), the traction being maintained for three to four weeks. Should pain then recur a plastic collar should be provided to limit neck movement. Also if bed rest was impossible a collar must be fitted and analgesics provided.

Central Protrusions in the Elderly

Central protrusions of the cervical disks were a common cause of mild spastic paraplegias in older people, often without sensory change. They caused symptoms by traction on the dentate ligaments, obstruction to the anterior spinal artery, and friction during spinal cord movements. Treatment was by traction, and later a plastic collar. The results were often very satisfactory. Surgery should be conservative, decompression followed by the fitting of a collar being sufficient.

After the contributions of the opening speakers there was a short discussion.

The Food Standards Committee of the Ministry of Food has considered and adopted a report on lead in foods. This states that lead is one of the most widespread and serious of the metallic contaminants of food and drink. Many foods and water contain naturally small amounts of lead; shell-fish may ingest and absorb lead compounds present in sea and estuary water; and lead can be inhaled in atmospheric dust. Some of these sources are uncontrollable but others are attributable to human agency and can be regulated. Lead arsenate is used as an insecticide for spraying apple and pear trees and occasionally for spraying soft fruit. Contamination from this source is not of course confined to the raw fruit but is liable to occur whenever these fruits or products derived from them are used in the preparation of foods—e.g., in the manufacture of cider, of apple pectin, and of soft fruit jams containing apple pectin. Contamination from containers is liable to arise with canned foods or where lead pipes are used to convey water, beer, cider, etc. The extent of contamination of canned meats varies according to the type of container, there being a higher rate of contamination from cans with vent holes which require soldering.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Male Infertility

SIR,—The letter from Dr. F. N. Valdez on this subject (January 12, p. 106) cannot be allowed to pass without comment. I have little desire to question the principles and practice of Roman Catholic theology, but I feel that to regard the production of a seminal specimen *for the purpose of investigating male fertility* by masturbation as a perversion of nature is surely ludicrous, especially as that theology rightly regards reproduction as a cardinal duty of the married couple. If reproduction is so important a duty, then clearly the institution of measures to promote it, when unaided it seems to fail, is equally important. That masturbation is in fact a perversion of nature is, of course, open to grave doubt, if only on the basis of the frequency of its occurrence (see A. C. Kinsey, W. B. Pomeroy, and C. E. Martin, *Sexual Behaviour in the Human Male*, 1948) in human males and in monkeys. In any case, the theological prohibition is clearly aimed at masturbation and other sexual acts employed for the purpose of obtaining pleasure but without reproduction. Masturbation for the production of a seminal specimen for medical examination is obviously not for pleasure—and, indeed, is more or less distasteful to many men. In my experience Roman Catholics have nearly always been able to obtain sanction to produce a masturbation specimen when proper application has been made to the priest.

It scarcely need be reiterated—for the point has been discussed often before—that seminal specimens collected by condom are utterly worthless for fertility estimation, while coitus interruptus is seldom of greater value, owing to the impossibility for most men to exercise the required control and acrobatic agility to ensure the entire ejaculate passing into the specimen jar. To imagine that the study of testicular biopsies and the estimation of urinary androgens and gonadotrophins will be of much help in establishing the fertility of men, in the absence of seminal examination, shows complete detachment from reality. The effort alone required to perform these studies, as compared with seminal analysis, is prodigious and obviously prohibitive, while entirely normal results from all three could be quite compatible with complete sterility as, for example, in cases of aspermia due to blockage of the ducts.

If Dr. Valdez is faced with insuperable difficulties in determining male fertility because of his inability to obtain masturbation specimens in certain cases, may I suggest that he will find the post-coital test far more simple and far more informative than all the testicular biopsies and hormone estimations ever could be?—I am, etc.,

London, W.C.1.

G. I. M. SWYER.

SIR,—Dr. F. N. Valdez (January 12, p. 106) is evidently unaware of a very simple method of collecting semen apart from the Huhner test. The patient is given a small test-tube and is instructed to collect the semen from the amount which nearly always flows from the vagina after coitus. This method is in conformity with the tenets of the Roman Catholic Church and is satisfactory.—I am, etc.,

Dublin.

BETHEL SOLOMONS.

Diagnostic Unit for Practitioners

SIR,—I read with great interest the article by Dr. John H. Hunt (December 29, 1951, p. 1575). I should like to congratulate him on his courage and enthusiasm in developing the unit which he describes at a time when any such project is beset with difficulties at every step. He suggests, however, that small units such as this may have their place within the

National Health Service. So far as my own specialty, radiology, is concerned, I think any such development is to be deprecated. Multiple small units are inevitably costly and result in inferior work. He states that in three years 1,476 patients have been examined radiologically by a whole-time radiographer, although I am not quite clear if this number includes cases sent from other doctors. In larger departments a radiographer is able comfortably to examine 3,000 cases in a year. It has been my experience that in the small cottage hospitals there is frequently a wastage of personnel owing to the necessity of employing a whole-time radiographer who is not fully occupied. It is also my experience that the standard of radiography and the general usefulness of the department to the clinicians using it is seldom as good where a radiologist is only intermittently available as in those departments where a full-time radiologist is available at all times to give his advice and stimulus.

I do not wish to suggest that there are not strong arguments in favour of these larger departments being freely available to general practitioners. Used with a proper understanding of the limitations of radiology and the significance of radiological reports by the practitioner concerned, together with close personal liaison between himself and the radiologist, I think this direct access can be of great benefit to the patient.—I am, etc.,

Ryde.

JOHN H. L. CONWAY-HUGHES.

Shortage of X-ray Films

SIR,—Your leading article on this subject (January 12, p. 94) is the first reference to the fundamentals of the problem, the conflict between those who seek to sell film for hard currency and the voracious demands of the "free" Welfare State. Whatever the solution of the wider problem, the trials and frustrations of the present shortage are the despair of those in charge of x-ray departments. The standard of work suffers because particular types of film are not available, and shortage of smaller sizes compels the use of larger films than necessary. Shortage of the usual chemicals in the dark-room again spoils good film. Endless time and energy are wasted by everyone in desperate efforts to get some film somehow from somewhere. In the Eastbourne Group we have up to now had an open department to which the general practitioner could refer cases direct—a much-appreciated and, in my experience, seldom-abused facility. Under the present conditions, we have had to withdraw this service indefinitely, except for accidents. You point out many ways in which film can be saved. The fact is that, even when all this is done as far as possible, there still remain endless difficulty and frustration in obtaining sufficient film.—I am, etc.,

Eastbourne.

E. OWEN FOX.

SIR,—Your leading article on the shortage of x-ray films (January 12, p. 94) is a fair and accurate analysis of the position. Experience has proved that more and more patients are being referred for x-ray examination, and with the refinement of the radiological diagnosis and the discovery of new fields of radiological investigation the expansion will continue indefinitely. In view of our economic position, however, we are likely to suffer from a shortage of x-ray films for years to come.

The solution of the problem lies perhaps in a radical change of radiographic technique. Our present radiographic method is extremely wasteful. There is no reason why most of the radiographic pictures should not be obtained by photographing on a small plate the screen image, as in mass radiography. A few years before the war I submitted to a leading x-ray manufacturing firm a design for an apparatus suitable for that purpose. The screen image is photographed by means of a suitable camera on a film $3\frac{1}{4}$ in. by $2\frac{1}{4}$ in. (9 by 6 cm.). The camera can be focused in such a way that the whole of the photographic film is made use of, irrespective of the size of the part of the body examined. Thus the image of a wrist, for example, would be less reduced than, say, the image of a spine. The focusing, however, would

be entirely automatic. The photographs could be examined either directly or by means of a magnifying glass or an enlarger.

Not all x-ray installations would be powerful enough to produce screen images bright enough for instantaneous photographic exposures, but all stationary parts of the body could be examined with photographic exposures not longer than a few seconds even when only a small x-ray apparatus is available. Such a change in radiographic technique is bound to follow in any case as a logical development of the amplified x-ray beam, which is on the way and may as well be adopted now.

The saving in x-ray films, the cost of which is continually increasing, would be enormous, as the small photographic plates would cost on an average less than a tenth of the cost of full-size films and the outlay on the camera and suitable enlarger would be recovered in a short time.—I am, etc.,

Guernsey.

A. ORLEY.

Radiography and Ruin

SIR,—Are x-rays "essential"? Surely the answer must be no. Surely this addiction to radiography is just another symptom of the vice of our time, which threatens to bring our civilization to ruin. Thank goodness your leading article on the shortage of x-ray films (January 12, p. 94), ending with the words "food for the fit or films for the failing?" indicates that one journal at any rate is aware of the danger. We fret about atomic bombs and the risk of another war, oblivious apparently of the danger that overrides all else—successful treatment at long last come to fruition in a world of men utterly unfitted to receive it. Thus medical science to-day is harnessed to produce dysgenic breeding of humans, destruction of the "lower" animals, impoverishment of the land, pollution of the water, and inordinate world overpopulation, the precursor of a cataclysmic fall.—I am, etc.,

Buxted, Sussex.

W. R. E. HARRISON.

"Idiopathic" Scoliosis

SIR,—It is good to find Mr. Denis Browne (December 29, 1951, p. 1584) lending the weight of his authority to the contention that infantile scoliosis can and should be diagnosed and treated within a few weeks of birth, instead of encountering either unwarranted optimism or equally disastrous pessimism, such as occurs in many clinics.

The diagnosis is certainly not easy, but the existence of a lump on one side of the chest, which is caused by rotation of the spine forcing the angles of the ribs back one side, should always be considered an indication for radiography of the whole spine on a single large film, on which the primary curve and secondary curves of later development can usually be seen and their relative compensation estimated. In the very young infant the original curve can be expected to disappear; once sitting has begun, it may be possible only to ensure that two curves, or a series, balance each other, so that the general axis of the spine is vertical.

As regards splinting: for over 15 years the writer has been using the wooden bed designed by Schede, of Leipzig, which consists of a base of plywood, padded with lamb's wool, covered with "rexine," so as to be washable; from this base project three well-padded struts, one to compress the ribs on the convex side and the other two to exert counter-pressure on the opposite arm and thigh respectively. The child is held up the centre of the bed by padded straps. Traction to the ankle of the concave side can be applied by a bootie tied to an iron loop projecting from the bed. To increase traction the foot of the bed can be raised at night on a box; while by day, as the child develops, it can be given a view of the world for increasing periods by raising the head-end. Every wriggle by the infant represents an exercise in active correction of its deformity. It is not easy to demonstrate details in a photograph, but the writer could lend a small model to any practitioner interested. This type has been constructed in the Bath orthopaedic splint workshop for many years.—I am, etc.,

Edinburgh.

M. FORRESTER-BROWN.

Megaloblastic Anaemia in Indians.

SIR,—With reference to Professor S. Chaudhuri's experiences with vitamin B₁₂ in megaloblastic anaemia in India (October 6, 1951, p. 825), may I be permitted to point out that I have shown in a certain proportion of cases of megaloblastic anaemia in Indian women in Fiji during pregnancy and the puerperium that, apart from a small temporary reticulocytosis with large doses, there is no marrow reversion or haematological response to vitamin B₁₂? On the other hand, there is a good response to folic acid. These results have now been confirmed (*J. trop. Med. Hyg.*, 1951, 54, 89) by using the vitamin B₁₂ preparation known as "normocytin." There is at present no apparent difference between the cases of megaloblastic anaemia associated with pregnancy and the puerperium which respond to vitamin B₁₂ and those which do not. As a rule, however, the cases which require folic acid are more severe, and would have proved fatal in the past, a fact which is apparent in the number of deaths registered in Fiji from "anaemia" in Indian women. This becomes apparent from examination of hospital records. Moreover, many of the cases which need folic acid are misdiagnosed, as the clinical picture may resemble typhoid or severe puerperal sepsis owing to the associated high fever. Unless these cases are sought for, the occurrence of megaloblastic anaemia associated with the puerperium and not responding to vitamin B₁₂ may be missed, and deaths may be ascribed to some other cause.—I am, etc.,

Suva, Fiji.

P. E. C. MANSON-BAHR.

Malaria

SIR,—In spite of Sir Bennett Hance's disarming kindness to my antiquity, I feel I must join issue with him on one or two points in his letter (January 12, p. 104).

Of course, nobody who has studied a section of brain from a case of cerebral malaria would deny that the intravenous route is the first indication for such an emergency. But for the chronic case I suggest that the intravenous route, like the oral, has the disadvantage of resulting in too rapid absorption with proportionally shorter stay in the body, a case analogous to that of penicillin before the invention of absorption-delaying preparations of this remedy. This view is based on the undoubtedly better results which I obtained by intramuscular injection than by the oral route (though I did try very hard to ensure best results by the latter method) and on the fact that symptoms of cinchonism were very rare in my cases; it is subject to correction by experimental evidence on concentration levels of quinine in the blood serum.

I agree that quinine causes necrosis at the site of the injection, but saw no disadvantage in this provided that the injection was made deeply into the gluteal muscles and precautions were taken to prevent regurgitation of the drug along the needle track. I would suggest that the painful nodules which Sir Bennett mentions are a good argument for drilling a good technique of intramuscular injection into the medical subordinates concerned. After all, intramuscular injection is used for the administration of many other drugs besides quinine, and emphasis on good technique would affect the comfort of far more people than those requiring treatment for malaria.—I am, etc.,

London, S.W.1.

L. W. HARRISON.

Treatment of Tropical Ulcers

SIR,—Mr. H. D. Obrien writes (December 29, 1951, p. 1544) that the results of treatment of tropical ulcer are still unsatisfactory. He has improved on our therapy by the addition of penicillin and skin-grafting, both of which were unavailable in our series (Marsh, F., and Wilson, H. A., *Trans. roy. soc. Trop. Med. Hyg.*, 1945, 38, 259). Dr. Obrien writes that his results do not differ much from the best results in the literature surveyed. Actually the method he describes, is far from simple and is very time-consuming for a medical officer working with

little or no skilled help. Dr. Obrien mentions "zipp," which was devised by J. C. R. Buchanan and W. K. Connell (*Trans. roy. soc. Trop. Med. Hyg.*, 1933, 27, 239) and is still very useful. We found that powdered potassium permanganate applied in a very thin layer over the ulcer under medicated gauze and a light plaster bandage rapidly cleared up the most obstinate cases. The application, dressing, and plaster bandage were removed and fresh material applied at the end of 10 days or a week. The majority of our cases were healed in two weeks by this treatment. Dr. Obrien improved the diet of his patients and kept them in hospital. Our patients were all treated as outpatients and their diet was not improved, much as we would have liked to supplement it. Filth, food, friction, fuso-spirillosis comprise what is known of the aetiology of tropical ulcer, even at the present date. I agree that great numbers of these cases occur still because the "seed" and the "soil" have not decreased, even in this modern world. But more than one effective and simple method of treatment—as Dr. Obrien seems to acknowledge—now exists; so progress has not altogether been smothered.—I am, etc.,

Epping.

FRANK MARSH.

Epigastric Hernia and Dyspepsia

SIR,—Many of the coal-miners in my practice have emphysema. A number of them have associated dyspepsia. Their medical cards are filled with such entries as bronchitis, catarrh, bronchitis, 'flu, pneumonia —, dyspep. gastritis, gastric catarrh, ? peptic ulcer, haematemesis, etc. (Also the chills, myalgia, neurasthenia, debility, anaemia, neurosis, "the pinched look and don't-want-to-go-to-work feelings" which I take to be the forerunners of established silicosis.)

Many of the dyspepsia cases have had hospital investigations and barium-meal radiographs. The chest condition is invariably overlooked and just occasionally a gastric ulcer is reported. They are seldom cured and depend on alkalis for relief. On careful digital palpation of the epigastrium between the xiphisternum and navel in the midline, I find many have unsuspected epigastric herniae. The herniae are often less than the size of a pea, and between attacks are difficult to feel. Once the lump is felt there is usually no doubt. The patients often say, "That's the spot, Doctor," though they may not have been conscious of it before. I attribute this emphysema-epigastric-hernia syndrome to the chest becoming barrel-shaped, with an increase of the circumference of its lower part. The upper recti may be pulled apart at the midline, and a chronic cough, with increased action of the diaphragm, completes the job.

I regret, owing to the protracted rebuilding of the local cottage hospital, that I have been unable to get the majority of these cases confirmed by operation. I feel it may be of interest to record these findings and to suggest that emphysema and epigastric herniae may be the real causes of a great number of cases of ill-defined recurrent dyspepsia and gastric ulcer.—I am, etc.,

Chasetown, near Walsall.

ROY HOUGHTON.

Cough Fracture

SIR,—In connexion with the papers on cough fracture by Dr. J. B. Mitchell and Dr. N. Wynn-Williams (December 22, 1951, pp. 1492 and 1494) the following case may be of interest:

The patient, a young man 18 years of age, was first seen on September 19, 1950, with a history of a productive cough of about two weeks' duration, some lassitude, and loss of weight. An attack of pneumonia in childhood was given as previous history. Clinical examination and chest radiograph revealed bronchitic changes in both lower lobes, especially on the right side. The patient was instructed in postural drainage exercises, and advised to return to the chest clinic if his symptoms failed to clear up in a few weeks.

He was not seen again until referred to the clinic by his general practitioner on October 17, 1951. About two weeks previously he had developed some cough and sputum and complained of pain in

In established nasal infections

'PENDEX' *provides*

**prompt and
prolonged
vasoconstriction**

plus

**the potent
bacteriostasis
of penicillin**

Penicillin (unlike the sulphonamides) is not inhibited by the presence of pus, and has proved highly effective both in acute sinusitis and in flare-ups of chronic sinusitis.

'Pendex'—providing the bacteriostatic action of penicillin, plus the aeration and drainage effected by 'Paredrinex'*—has proved particularly useful in such conditions.

'Pendex' can be used to irrigate the sinuses, followed by the displacement technique; or it may be administered by tampon.

* 'Pendex' contains 1% 'Paredrinex' (p-Hydroxy Amphetamine Hydrobromide, S.K.F.)

PENDEX

— the penicillin-vasoconstrictor for intranasal use

Available in 15 ml. (½-oz.) bottles, on prescription only

his right shoulder and back and down his right arm. His temperature had been elevated, and a pleural rub was heard on the right side at that time. He was given a course of sulphamezathine tablets and put to bed for one week. When seen at the clinic, his general condition was good, and no physical signs could be detected in his chest. A radiograph of his chest (P.A. view), however, revealed a recent fracture of the lower third of his first right rib. It was noted that the first rib on the left was apparently missing, apart from a rudiment discernible on the film. On further questioning, the patient stated that during a fit of coughing some two weeks previously he experienced a sudden fairly severe pain down his right arm which did not leave him for some time. When he was being examined the same kind of pain could still be elicited by pressure on the first right rib. A follow-up radiograph on January 9, 1952, shows good callus formation round the fracture.

It has been stated in one of the papers mentioned above that fractures of the first rib have no relation to cough and are usually asymptomatic. The case described above does not seem to fit in with this. In view of the malformation of the corresponding rib it remains a matter for speculation whether a congenital weakness was present as a predisposing factor in the fracture described.

I wish to thank Dr. John Glen for permission to publish this case, and for his advice and help in connexion with it.

W. E. ZUNDEL.

Post Hoc, Propter Hoc Reasoning

SIR,—I have only just had the opportunity of reading the excellent article by Drs. B. F. Swynnerton and S. C. Truelove (November 24, 1951, p. 1243). That gastric ulcers frequently go malignant is one of the many doubtful theories which have been handed down from textbook to textbook without due inquiry, to clog the minds of generations of unfortunate students. *Post hoc, propter hoc* reasoning has been the curse of scientific progress down the ages. Because we bear certain superficial resemblances to the ape it must be assumed that we have descended from him. Because a carcinoma develops at the site of an ulcer it must be assumed that the two are dependent one upon the other. Because fibro-adenosis of the breast, at a certain stage, is closely allied histologically to carcinoma, it must be called a precancerous condition, and the breast is amputated, while there is no shred of clinical evidence that carcinoma develops any more frequently in these than it does in the normal breast.

There is only one way of forming criteria of malignancy, and that is by studying the living patient, and the pathologist who takes the trouble to follow up his patients instead of going through the years with his eye glued to the microscope or the pathological specimen is the one from whom real advances are to be expected. The great achievements of the old pathologists came from just those men who combined a study of pathology with a study of clinical medicine, and one greatly deplores the present tendency to turn out so-called specialist pathologists who have neither knowledge nor experience of clinical medicine. This present tendency towards the narrow training of specialists will be the ruination of British medicine unless nipped in the bud. We have always prided ourselves on our balance and common sense, and if we are unable to "walk with kings—nor lose the common touch," then it is the kings to whom we should say farewell.—I am, etc.,

Nairobi.

R. T. BURKITT.

Simultaneous Haemorrhage and Perforation of Meckel's Diverticulum

SIR,—The article by Drs. John N. Walton and Norma D. Lill (January 12, p. 88) prompts me to report the following case where severe bleeding was associated with a perforated peptic ulcer of Meckel's diverticulum.

A boy, aged 8 years, was admitted on May 9 with a diagnosis of acute appendicitis. There was a history of diarrhoea for four days. On the day previous to admission he had developed lower abdominal pain, but had not vomited. No other relevant history

could be obtained. When examined the child was crying quietly. The temperature was 100° F. (37.8° C.) and pulse 84. There was generalized abdominal tenderness and rigidity, most marked in the right iliac fossa. Occasional bowel sounds were heard on auscultation. There was marked tenderness in the recto-vesical pouch on rectal examination.

Operation.—When the abdomen was opened through a McBurney incision a considerable amount of blood-stained fluid was present in the peritoneal cavity. The appendix was normal. A Meckel's diverticulum, situated about 12 in. (30 cm.) from the ileo-caecal valve, showed a circular perforation nearer the base, exuding intestinal contents. A small artery passing from the mesentery to the diverticulum was bleeding freely in the mesenteric edge of the perforation. The bleeding was controlled by ligation of the vessel in the mesentery and the diverticulum was excised. The patient had an uneventful convalescence and was discharged on May 30.

Specimen.—Examination showed the presence of gastric mucosa in the distal half. The remaining mucosa was of the small intestine type. The perforation was situated on the intestinal area about 1 cm. from the edge of the gastric mucosa.

The main points of interest in this case are the unusual association of haemorrhage and perforation, the absence of evidence of passage of blood in the stools (because of involvement of the remnant of the vitello-intestinal artery, haemorrhage had occurred into the peritoneal cavity and not into the lumen of the gut), and the site of the perforation.—I am, etc.,

Balham, S.W.12.

J. BURKE.

Congenital Dermal Sinus and Meningitis

SIR,—Drs. B. S. Cardell and Bernard Laurance have done service in reporting (December 29, 1951, p. 1558) their interesting case of congenital dermal sinus associated with fatal meningitis, since, although a rare condition, it will be met with in paediatric practice from time to time and if recognized early can be saved. They refer to two cases of my own which I included when reporting eight cases of spinal epidural abscess in 1938. In one there was an epithelized track from the skin to the dura; in the other, a similar track led down to an infected intra-spinal epidermoid cyst; and, in both, the superficial end was represented by no more than a minute punctum. Since that time I have met with two more cases of intra-spinal dermoid or epidermoid cyst (one of each) connected to the overlying skin by an epithelized track, the arch of the corresponding vertebra being deformed or bifid in each case.

One of my objects in writing this note is to issue a warning against regarding the removal of one of these innocent-looking sinuses as necessarily a simple operation. In fact the surgeon may find himself among the components of the cauda equina, and unless familiar with neurosurgical techniques he may precipitate the very complication he was hoping to prevent. Of the 35 cases quoted in their paper no less than 17 had dermoid or epidermoid cysts lying within the spinal canal.

It seems to me that the origin of all these sinuses is not necessarily always the same. Those overlying the sacro-coccygeal region may well be modified forms of pilonidal sinus, as Walker and Bucy suggest, the neural crest ectoderm and cutaneous epithelial ectoderm never having completely separated. The opening is very small, admitting no more than a bristle, and can easily be overlooked by even the most observant mother. But some of the more highly placed sinuses must surely be forms of spina bifida. Of the 33 sinuses overlying the spinal column quoted by the authors 19 were associated with bony defects in the vertebral arches of about the corresponding level, and seven more said to have no bony defect were, nevertheless, connected with the meninges. Some were accompanied by a tuft of hair, an area of pigmentation, or a capillary angioma; and seven had abnormalities of the cord or filum terminale. All these features would fit in with spina bifida occulta, but with a sinus in addition.

In the lesion under discussion infection of the sinus leads inevitably to infection within the spinal canal, which, depending on the deep connexions of the track, leads either to a

primary spinal meningitis or, as the result of infection of the spinal epidural fat or of an intra-spinal cyst, to secondary meningeal irritation or frank meningitis. From the experience of my own 10 cases of spinal epidural abscess, together with others I have seen with colleagues, I would suggest that the really important lesson to be learned is that where a child, ill, feverish, and fretful, complains of pain in the back, or is observed to use it awkwardly—not bending it when picking up something off the floor—and on examination resents even the slightest passive flexion yet not of hyperextension—thus differentiating the case from tuberculous disease of the spine, which it may closely mimic. Think of the possibility of ascending spinal meningitis and look for the minute opening of such a sinus. The sinus may be actively inflamed, as in the case of Drs. Cardell and Laurance, but there may be no inflammatory reaction whatever: the symptoms may be gradual, fulminating, or intermittent, and the latter, like the case reported, may finish with a fulminating attack, the anxiety then being vascular thrombosis affecting the cord. If an x-ray picture shows a bifid or ill-formed spine the sinus is even more certainly the responsible lesion. The spine tends to become more and more extended, and head retraction develops, yet a little extra passive extension is tolerated—but not a degree of flexion. This “unfolding” of the spine is very characteristic of ascending spinal meningitis. It is wiser not to perform a lumbar puncture, since the needle may transfix an epidural abscess and carry pus into the subarachnoid space, but a cistern puncture will give information regarding cells and organisms. Should the case be seen before pus has formed sulphonamides and antibiotics may abort the condition, but where pus is suspected or the case is not responding to conservative treatment operation is clearly called for, and it will almost certainly mean a laminectomy.—I am, etc.,

Birmingham.

F. A. R. STAMMERS.

The Common Cold

SIR,—Treatment for this malady is being increasingly solicited by the public, who previously were content to endure this affliction stoically or utilize one of the remedies prescribed by folklore. I believe that it has been established that this infection is due to a virus of small molecular size. As the natural immunity conferred by an attack is of short duration vaccine treatment is presumably foredoomed to failure. Virus infections seem resistant to our present range of medicines except for some of the larger molecular viruses which are sensitive to an odd one of the latest antibiotics. If one of these is found which is effective against the coryza virus it is probable that its expense will make its use economically impracticable for at least several years.

I would therefore venture to suggest that the money at present being spent on research on the common cold would have been better devoted to research on the nature of viruses. Any treatment apart from general constitutional measures which can be utilized at present is at the best palliative and, I fear, too often actively harmful. It seems as meddlesome to use ephedrine or other vasoconstrictors in what is an acute inflammatory state as it would be to use ice packs in the treatment of a boil. I think the use of these applications often contributes to the incidence of sinusitis, especially in the mucopurulent stage where a blocked ostium is opened after a negative pressure has become established or there is a pabulum of inflammatory exudate present in the sinuses. It is in this stage these remedies are supposed to be especially efficacious.

The widespread opinion that colds are best left to take their course concurs with this view. A folklore remedy which seems more helpful is that of sniffing a salt solution. This seems analogous to using salts in acute dysentery, which was what I believe to be the best treatment available prior to the introduction of the sulphonamide drugs. In folk-medicine the essential oils in the form of a vapour—for example, eucalyptus, linseed, hops, and onions—figure

frequently in anti-coryza measures. It would be interesting to know if any essential oils can indeed influence the course of the coryza infection in any way and, if they do, what their action might be. Might they act by inducing hyperaemia?

In my own case, when sufficiently afflicted to desert stoicism I think I find some relief from hypertonic saline irrigations and also am almost persuaded that the duration of the mucopurulent stage is reduced.—I am, etc.,

Kirkham, Lancs.

J. SUTHERLAND.

Indian Remedies for Poor Memory

SIR,—I have never used or wished to suggest (*British Medical Journal*, October 6, 1951, p. 852) the use of the African drug *Catha edulis* therapeutically, and least of all for impaired memory, as Dr. D. A. Baird (December 22, 1951, p. 1522) alleges. I referred to it because its chemistry and pharmacology, as indicated in my references to the *Dispensatory* of the United States of America, may throw some light on the scientific investigation of the Indian drug *Celastrus panniculata* Willd.; both these drugs are derived from the same botanical family and have one of the alkaloids, celastrene, in common. Such botanical grouping often gives some suggestion of similarities (though not identity) in chemical and pharmacological properties, as those of *Atropa belladonna* L., *Hyoscyamus niger* L., and *Datura stramonium* L., all plants from the same botanical family—Solanaceae.

My mention of *Catha edulis* as an excellent stimulant beverage, without subsequent depression (in therapeutic doses), was based on Watt and Breyer-Brandwijk's references and particularly on Martindale's *Extra Pharmacopoeia* (1914, 1, 325), where catha is mentioned as a drug known for generations for its sustaining power, and the therapeutic (pre-narcotic) doses for its solid and liquid extracts are given. All beverages, including the caffeine-containing tea and coffee, can be harmful in overdoses or during prolonged misuse. Amphetamine, which is a cortical stimulant, can produce addiction and other toxic effects and yet is a very valuable drug in narcolepsy and depressive states. The development of the scientific use of opium and some of its valuable alkaloids and the synthesis of amidone (“physeptone”) and pethidine (“demerol”) would have been impossible if the dangers of addiction or deleterious effects during misuse had stifled all research. The Indian drugs I mentioned have been very extensively and effectively used from the times of Charaka and Susruta, and are not known to produce any deleterious effects, and I trust that their scientific investigation will confirm the Indian and my own records.—I am, etc.,

Oxford.

SOHRAB A. E. HAKIM.

SIR,—I have been in communication with Dr. Hakim, and have suggested that a controlled clinical trial of *Celastrus panniculata* could be carried out here. Dr. Hakim has agreed to such a trial and I hope to be in a position to report our findings in the not too distant future.—I am, etc.,

Little Plumstead Hall,
Norfolk.J. V. MORRIS,
Medical Superintendent.

Danger of Extracting Many Teeth at Once

SIR,—I am more than pleased to see that Dr. I. E. Reichenfeld (December 8, p. 1406) is converted to my view: that nutrition, environment, and education are the key points in any campaign for better dental health. The good doctor must realize that the dental surgeon sees his patient generally for the first time when the mouth is already in a chaotic state and nothing short of extraction is of any use whatever. I have many, many, tragic mouths to deal with in patients of ages from 12 to 16 upwards, and with all the knowledge and skill in the world one can do nothing with a mouth-full of roots and multiple abscesses.

I will agree that Continental people are more conservative-minded, but I, in common with my colleagues, have had the melancholy duty of removing foul septic crowns and bridges from Polish, Italian, and other Continental patients. From

my own experience the conservation there is pursued to impossible and very dangerous limits. I have at the moment an Austrian gentleman who wishes me to construct a bridge upon a floating $\overline{7}$ across to a non-vital and rarified $\overline{4}$. A bridge is already carried on rather similar teeth on the right side.

There is no doubt that, given greater co-operation between medical and dental colleagues, much can be done, but I must restate this: although I know that medicine is already overburdened, the family doctor always sees the patient first and usually many years before the dentist.—I am, etc.,

Birmingham.

L. A. PHILPOTT.

POINTS FROM LETTERS

L-Noradrenaline

Mr. L. M. SPALTON (Bayer Products, Ltd.) writes: The statement in your annotation, entitled "Noradrenaline by Intravenous Infusion" (December 29, 1951, p. 1571), that the solution of noradrenaline in saline should be slightly acid, or should contain ascorbic acid, may well impose an unnecessary burden on the anaesthetist. Normal saline, if properly prepared, should always be slightly acid, and will be alkaline only if stored for a prolonged period in glass containers which release alkali. L-noradrenaline as manufactured usually contains an antioxidant in the ampoule, and will retain its potency for at least a year or two. If the contents of the ampoule are added to a saline solution which has become alkaline, oxidation will occur, but not for several hours.

Shortage of X-ray Films

Dr. JAMES F. BRAILSFORD (Birmingham) writes: Because we are short of x-ray films essential radiographic services are being jeopardized, but the reason why we are short of these essentials is because they are being extravagantly wasted, chiefly by those clinicians who fail to give adequate consideration to the need of the radiographic examination and to assess the true value of the evidence to the patient which this expensive service yields. If a careful census of films used were made and their merits assessed it would be found that the percentage wastage was in the region of over 70 and often over 90, and the tuberculosis and chest service would easily top the list in waste. For over 10 years I have been repeatedly urging in and out of the medical journals the need for the exercise of reasonable care in the use of x-ray films. I forecast the present outcome before the wastefulness of the present service; it may have come sooner but for this cry in the wilderness. I saw the same waste in the U.S.A., and even against opposition did not miss any opportunity of drawing attention to it.

Ruptured Spleen

Dr. J. MURRAY BLACK (Dunfermline, Fife) writes: Recent articles in the *British Medical Journal* by Sir James Learmonth (July 14, 1951, p. 67) and Mr. Harold Edwards on splenectomy stimulated me to look up the records in the Dunfermline and West Fife Hospital regarding the incidence of traumatic rupture of the spleen. I find that during the year ended November, 1951, five cases were operated on. Considering that A. K. Hendry (in *British Surgical Practice*, vol. 8) gives the London Hospital figures as 32 cases in 34 years, the occurrence of five cases in one year at a small provincial hospital must be unusual.

Initiative

Dr. P. C. LEWIS (Hove) writes: I was called out one evening to see a little boy, and on arrival found that he was suffering from sore throat and earache. The auditory canal was full of wax and the drum head thus obscured. I had not brought my ear syringe with me, and it was essential to remove the wax. As no syringe was available it occurred to me that the little boy might have a water pistol. Discovering that one was in the house (confiscated for obvious reasons), it was brought forward and one shot displaced the wax to reveal a red but not bulging drum.

Correction

Dr. S. RUSSELL JAMIESON writes that he omitted to thank Mr. Peter Gaskill, of the Department of Education of the Deaf at Manchester University, for information contained in paragraphs two to five of the discussion in his paper on "Tuberculous Meningitis" (*Journal*, January 12, p. 84).

Obituary

NIGEL CORBET FLETCHER, O.B.E., M.B.

Dr. N. Corbet Fletcher, formerly Surgeon-in-Chief of the St. John Ambulance Brigade, died in London on December 21, aged 74 years.

The son of the late Dr. J. Corbet Fletcher, Nigel Corbet Fletcher was educated at Merchant Taylors' School; Queen's College, Cambridge, to which he won a classical scholarship; and University College Hospital. Qualifying in 1904, he graduated in the following year. He won the Fellowes Gold Medal at University College Hospital, where he held resident posts as house-physician and senior obstetric assistant. In 1906 he started practice in Hampstead, where he worked to within a few days of his death. His reputation grew quickly and he was soon respected and admired throughout the whole district. Fletcher was a fine athlete, and played Rugby football for his school, his university, and for Middlesex. He was twice capped for England, in 1901 and 1903. In 1908 he married Mabel Isabel Browne. His married life was ideally happy, and it was a great blow to him when his wife died in 1942.

Major A. C. White Knox, Surgeon-in-Chief of the St. John Ambulance Brigade, writes: Corbet Fletcher's great hobby was the St. John movement, and he gave his first lecture for the association in 1908 to a class of employees of the old L.N.W. Railway. He was associated with the late Sir James Cantlie in teaching first aid at the Regent Street Polytechnic and the College of Ambulance. In 1915 he took over the answering of queries in the magazine *First Aid*, and 13 years later became the honorary medical correspondent to the Order's own magazine. His concise and sometimes pungent remarks in these magazines made readers look forward with interest to next issues. He lectured and examined many classes in first aid and home nursing for the railways, police, and many other large organizations where a knowledge of first aid was becoming essential. In 1916 Corbet Fletcher became divisional surgeon to the Hampstead Division of the No. 1 (Prince of Wales's) District. He was promoted to Assistant Commissioner and later to Surgeon-in-Chief, a post which he held from 1936 to 1950. He wrote numerous books on first-aid work, and was awarded the O.B.E. for his services to the movement. He held the Service Medal, and between 1918 and 1937 was made Honorary Associate, Officer, Commander, and finally Knight of the Order of St. John.

In the 25 years that I knew Nigel Corbet Fletcher, or "N.C.F.," by which initials he was known throughout the whole St. John world, I would say that his outstanding qualities were a lovable nature, hidden sometimes under a gruff exterior, and a great courage which carried him forward under the difficulties of failing health. His name is a landmark in the first-aid world, and his work will stand for many years to come as a great example of the St. John motto, *Pro Fide—Pro Utilitate Hominum*, "For the Faith and For the Service of Mankind."

R. FOSTER KENNEDY, M.D., F.R.S.E.D.

Dr. Robert Foster Kennedy's death on January 7 was recorded in last week's *Journal* (p. 165).

Dr. Robert Marshall writes: The first determining point in Foster Kennedy's career was when he was appointed house-physician at the National Hospital in

Queen Square, at a period when it was rare for graduates of the provincial universities to obtain even a resident appointment in London. The second was when he embarked for America to establish there the principles and precepts of British neurology which he had learnt so thoroughly. He was a man of dynamic energy and found time in his full life for many and varied activities. After his death the *New York Times* paid tribute to him in these words:

"One of the leading medical personalities of the United States and the world for many years, Dr. Kennedy was more than an outstanding physician or neurologist. He was a scholar and a wit, connoisseur and philosopher, an accomplished orator and raconteur. The mere announcement that Foster Kennedy was to deliver an address or participate in a discussion was sufficient to assure a lecture hall overcrowded by fellow-physicians, whom he never failed to delight with his original point of view, his fresh approach to a problem, his *bons mots* and aphorisms, pronounced in a faint Irish brogue. The medical fraternity came to regard him as a modern version of a Delphic oracle who always could be counted upon to highlight the essence of a subject with a trenchant quotable phrase."

This just and kindly appreciation of him gives the reader some idea of his amazing charm and of what a delightful person he was, but to see Foster Kennedy at his best was to see him at the bedside of a sick person. There he was a simple, kind, and gentle man, quick to appreciate the patient's point of view, and leaving nothing undone for his comfort and his welfare. If, as has been said, one can achieve success by being clever or by being kind—and one can always be kind—his skill and his cleverness were transcended by his unfailing kindness. When he was elected a doctor of science, *honoris causa*, of the Queen's University of Belfast, the dean of the faculty reminded us that he had served in the first world war with the rank of a British major in a French military hospital, and was awarded the Military Cross. He had also obtained special recognition by learned societies in France, Sweden, Hungary, Cuba, and Mexico, as well as London and Edinburgh. Better still, he had made friends all over the world, and nothing delighted him more than to entertain them royally in his beautiful American home. Ulster can indeed be proud of Robert Foster Kennedy.

The sudden death of Dr. W. J. MCL. BAIRD, of Blackpool, on October 29 at the age of 69, came as a great shock to his many friends and colleagues. He had made what was apparently an excellent recovery from two serious operations the previous year, and all his friends felt that his wonderful vitality would carry him through many years to come. William Joseph McLearn Baird studied medicine at Queen's University, Belfast, and at Dublin, graduating M.B., B.Ch. in 1904. He went into general practice in Blackpool, where he was the last of the general-practitioner surgeons in the area. He had been on the staff of the Victoria Hospital from 1910 to 1948, when he retired from the active surgical staff to become honorary consulting surgeon. In the 1914-18 war he served in Mesopotamia, and was attached to the 32nd British General Hospital. On returning from the Middle East, in addition to running a large general practice, he resumed his surgical work at the Victoria Hospital, and also had charge of one of the auxiliary military hospitals established in the town. As honorary secretary of the Blackpool Division of the B.M.A. from 1912 to 1923 he took an active part in local medical politics in the early days of National

Health Insurance. He later held office as chairman of the Division, and was a member of the insurance committee and panel committee. At the time of his death he was a member of the Blackpool executive council and the local medical committee. He was a J.P., president of the local Ulster Association, and had been a member of the borough council for a number of years. He leaves a widow, to whom every sympathy is extended.

A colleague writes: "Mac," as he was known to his friends, will be much missed. He was a very good companion, and to travel with him was a most enjoyable experience. His likeable personality always asserted itself in the end, even on occasions where controversy and somewhat acrimonious argument had been prevalent. A true son of Ulster, like so many of his fellow countrymen he loved to be "agin the Government" at times, and thoroughly enjoyed a spot of bother.

Lieutenant-Colonel EDWARD VICTOR HUGO, formerly of the Indian Medical Service, died on December 24, 1951, after a short illness at his home in Richmond, Surrey. Born in 1865, he was educated at Foyle's College, Londonderry, and received his medical training at St. Bartholomew's Hospital, qualifying in 1889 and graduating M.B., B.S. (with honours and gold medal) in 1890. His postgraduate studies gained him many distinctions which served him well in his future career in the I.M.S. He joined the Service in 1892, and in the 30 years of his life he devoted to it there were ample opportunities for the development of his personal and professional abilities to the fullest degree. He was a member of the Waziristan expedition, the Chitral relief force, and the Malakand field force, and he took part in the siege of Chakdara. He was mentioned in dispatches for his work on the N.W. Frontier in 1897-8. His special interest was surgery, and in 1908 he was elected professor of surgery at King Edward's Medical College, Lahore, a post which he held until 1914, when he reverted to military duties. As senior medical officer in the hospital ship *Gascon* he was present at the Dardanelles landing. In 1916 he became consulting surgeon, Mesopotamian Expeditionary Force. He was appointed C.M.G. in 1917, having previously been mentioned in dispatches. After the war he returned to the chair of surgery in Lahore, where he remained until he retired in 1922 and came to live in Richmond. After leaving India he served for several years as a member of the medical board of the India Office, and he took an active interest in the work of the B.M.A., becoming chairman of the Richmond Division and president of the Surrey Branch in 1934-5, besides finding time to support the local Red Cross, the Royal Hospital, Richmond, and the Royal National Lifeboat Institution, which last year bestowed on him its highest award, the gold medal. Colonel Hugo married in 1909, and his widow survives him.—L. H. W.

Dr. PERCY CLIFT PEACE died at his home at Burry Port, Carmarthenshire, on January 1, aged 71. Born at Sheffield, he studied medicine at University College, Sheffield, qualifying in 1903. After serving as senior house-physician at the Sheffield Royal Hospital and resident medical officer at the North Evington Infirmary, Leicester, he went to Wales in 1908 and entered practice in Tylorstown, Glamorganshire, in the mining district of the Rhondda Valley. He continued his general practice in that town for 16 years, and gained a high reputation among his colleagues and his patients for his work. He took an interest in the work of the British Red Cross Society and in the St. John Ambulance Brigade, lecturing and examining for both bodies. In 1924 he went into practice in Kidwelly, Burry Port, and district and carried on his life work among the people of Wales for a further 27 years. He lived in Kidwelly until 1947, when he continued his practice from the neighbouring town of Burry Port, leaving his partner in charge at Kidwelly. It was in Kidwelly that his work with the British Red Cross

SUCCESSFUL TREATMENT OF VARICOSE ULCERS

RECENT clinical trials further confirm that Viacutan (1% silver dinaphthylmethane disulphonate) is an extremely powerful antibacterial and healing agent in the various types of varicose ulceration. The bacterial infection of the ulcerated area which leads to enlargement and deepening of the ulcer almost invariably yields to applications of Viacutan.

The success of Viacutan is due to its unique attributes—it is active against both Gram-positive and Gram-negative organisms even in the presence of blood, pus and serum, and penetrates deeply into the tissues without destroying them. On the other hand it actively promotes cell-growth, with healthy granulation.

Tight and firm bandaging of the whole leg is essential in treating ulcers with Viacutan, and the after-care is highly important, but for all cases, suppression of infection and promotion of healing with Viacutan is of paramount value.

Viacutan

Control of the night attack!

Franol has been found most effective in maintaining a constant control of the bronchial asthmatic patient. As well as ensuring relief of symptoms it provides confidence: and this helps to solve a problem which is so often psychological. The dose is one tablet b.d. or t.d.s.

FRANOL

BAYER

PRODUCTS LTD, AFRICA HOUSE, KINGSWAY, LONDON, W.C.2

A new formulation of 'Cetavlon'—

the quaternary ammonium compound which is already well known to the medical profession as a bactericide and detergent.

'CETAVLEX' CREAM, containing 0.5% 'Cetavlon' (Cetrimide B.P.) is a most useful antiseptic application for controlling infection in wounds and burns and for treating many skin infections. It may be used with advantage in the preliminary treatment of wounds of all kinds, and is an excellent first-aid dressing for eliminating infective bacteria and thus facilitating healing. As an antiseptic application to the hands prior to surgery or when dressing wounds, etc., the Cream forms an additional safeguard.

'Cetavlex' Cream will be found invaluable in everyday practice in hospitals, in the surgery, factory, or in the patient's home.

'CETAVLEX' CREAM

Society and the St. John Ambulance Brigade came to fruition, for he was appointed honorary life member and examiner for both. He took a lively interest in local affairs, and was a borough councillor from 1945 to 1947, when ill-health forced him to retire. Although crippled at an early age, he was able to take part in and was ever interested in sports, holding vice-presidencies of Kidwelly and Burry Port rugby football clubs and the Burry Port bowling club.

T.R.D. writes: As a general practitioner Dr. Peace was a very sound clinician and always put his patients' welfare in the foreground. His outstanding personal quality was courage, which sustained him through many difficult times and in the fight against increasing physical infirmity during the last 10 years. Though the struggle was prolonged and often grim, he maintained to the end his confident and cheerful bearing towards his patients. At home he was the wise and understanding father of a united family, always ready to take a kindly interest in their troubles and rejoice with them in their pleasures. He is survived by three sons of his first marriage and by his widow and a young son and daughter.

Dr. PERCY BERNARD SKEELS, coroner for the Metropolitan District of Essex, who died suddenly on January 5 at the age of 70, was educated at the Leys School, Cambridge, and was admitted as a solicitor in 1905. While still in legal practice he entered Guy's Hospital Medical School in 1917, and qualified medically in 1925. He was later deputy coroner to Dr. Guthrie in the County of London and also for the City of London, and in 1933 was appointed to the coronership, which he still held at the time of his death. In 1943 he was elected president of the Coroners Society, of which he was an active member, and he was also a member of the Medico-Legal Society and on the council of the Medical Protection Society. Skeels represented a rather unusual type of career, the solicitor who takes up medicine, and throughout his years of office as coroner he constantly showed his legal training in the scrupulous attention to detail which he maintained in the conduct of his court and which he infused into the pathologists who worked for him. At the same time his interest in medicine never flagged, and when an unusual case was reported to him he would often visit the Royal Society of Medicine to seek further information. Although he did not write much himself he was always willing to advise on medico-legal publications. His interests were wide. In his young days he played cricket for Guy's Hospital, and he was a keen ornithologist and horticulturist.—F. E. C.

The passing of Dr. JOHN PHILLIPS has taken from the ranks of the medical profession another of those ardent souls whose ambition it is to die in harness rather than to retire. Dr. Phillips was well past 80 before his last illness intervened to stop his working. He was born in 1866, the only son of Mr. and Mrs. William Laing Phillips, of Harrogate, and entered Edinburgh University as a medical student, graduating as M.B., C.M. in 1888. After being resident medical officer at Mount Vernon Hospital, Hampstead, and house-surgeon at Monkwearmouth and Southwick Hospital, he settled in practice in Southsea in 1894. In 1901 he was top of the poll for election as assistant physician on the reconstituted staff of the Royal Portsmouth Hospital, from which as senior physician he retired in 1921. Dr. Phillips joined the Territorials in 1908 and was a major in the R.A.M.C. when called up for home service in 1914. He was appointed to the Staff of the 5th Southern General Hospital, which was established at Portsmouth during the first world war, and in 1918 he was made cardiologist to the Ministry of Pensions for the Portsmouth area. His last illness, of 18 months' duration, was most bravely borne. In 1914 Dr. Phillips married Dorothy Mary, the daughter of the late Mr. and Mrs. Forbes-Leith, of Southsea. Much sympathy is extended to his widow.—M. A. K.

Medico-Legal

FORGOTTEN TOURNIQUET

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

On March 14, 1951, a bus conductor, aged 32, was admitted to Heatherwood Orthopaedic Hospital, Ascot, for an operation for the removal of a cartilage in his right knee. Apart from his knee injury he was in perfect health. He was brought into the theatre at 12.15 p.m. on March 16. The tourniquet, an Esmarch rubber bandage, had already been applied to his thigh by the anaesthetist. The surgeon, assisted by a registrar, then performed the operation, which lasted about 30 minutes. It was the last operation performed by the surgeon that morning. The anaesthetist left the theatre with the surgeon's consent before the end of the operation. The surgeon saw the patient taken from the theatre. Nobody removed the tourniquet. It was hidden by the theatre gown he was wearing and by towels.

When the patient recovered from the anaesthetic at about 1.15 p.m. he complained of pain in his leg, and the registrar saw him in the ward. He was given an injection of morphine but was very restless, having to be held in bed until after a second injection of morphine at about 3.30 p.m. It was not until 6.15 p.m., when a male nurse was straightening up the patient's bed, that the tourniquet was noticed. The nurse released it at once.

The patient was seen that evening by the surgeon, who found deep lines round his thigh and red areas where the tourniquet had been. Treatment was immediately instituted, and next day the patient was given a blood transfusion. He later began to vomit, and it was found that his kidneys were not functioning properly. Some sensation later returned in his right leg and he could move his toes, but as his kidneys still did not function properly he was transferred to Taplow Hospital to be under the care of a doctor who had special experience of such injuries. He got worse, however, and a week after transfer developed abdominal pain. An exploratory operation was performed on March 30, but no cause could be found, and he died on April 4, nineteen days after the injury.

At the inquest the pathologist who carried out the necropsy gave evidence that the organs of the circulatory system were pale, there was congestion of the vessels, and the heart muscle was flabby. Death was caused by pulmonary oedema, and the serous spaces contained an increase in fluid. The kidneys showed degenerative changes associated with damage to the muscles of the right leg following the prolonged application of the tourniquet, which had caused a band of necrosis in the muscle of the upper part of the right thigh with progressively less severe changes from there towards the knee. Other muscles in the body showed spontaneous bruising. The failure of the kidneys to function normally had produced a very great rise of urea in the blood.

The cause of death was recorded as uraemia and nephrosis (crush syndrome). A verdict of death by misadventure was returned.

Universities and Colleges

UNIVERSITY OF BRITISH COLUMBIA

Dr. Donald Hugh Paterson has been appointed Clinical Professor of Paediatrics in the Faculty of Medicine of the University. Professor Paterson graduated M.B., Ch.B.Ed. in 1916. He proceeded M.D. in 1928 and was elected an F.R.C.P. in the following year. Before returning to Canada in 1947 he was Consulting Paediatrician to Westminster Hospital, Consulting Physician to the Hospital for Sick Children, Great Ormond Street, London, and Lecturer in Diseases of Children in the University of London. He is Paediatrician in charge of the Children's Health Centre at Vancouver General Hospital and Consultant in Children's Health to the Metropolitan Health Committee of the City of Vancouver. He was elected F.R.C.P.(C.) in 1947.

INFECTIOUS DISEASES AND VITAL STATISTICS

Summary for British Isles for week ending January 5 (No. 1) and corresponding week 1951.

Figures of cases are for the countries shown and London administrative county. Figures of deaths and births are for the 160 great towns in England and Wales (126 in 1951), London administrative county, the 17 principal towns in Scotland (16 in 1951), the 10 principal towns in Northern Ireland, and the 14 principal towns in Eire.

A blank space denotes disease not notifiable or no return available.

The table is based on information supplied by the Registrars-General of England and Wales, Scotland, N. Ireland, and Eire, the Ministry of Health and Local Government of N. Ireland, and the Department of Health of Eire.

† Includes primary and influenza pneumonia.

‡ Includes puerperal pyrexia.

§ See "Census Changes" opposite.

Vital Statistics**Census Changes**

Population figures obtained at the 1951 census show that there are now 160 great towns (population over 50,000) in England and Wales instead of 126, and 17 principal towns (population over 30,000) in Scotland instead of 16. Therefore the 1952 figures for deaths, births, and stillbirths in these countries, published weekly in our Table, cannot be accurately compared with those for 1951, which are printed in italics. The 160 great towns in England and Wales have a population about 10% higher than the 126.

Uncorrected Notifications

The weekly figures of notifications recorded in the Table and depicted in the graphs on these pages are uncorrected figures and may sometimes differ considerably from the final corrected ones. A case in point is diphtheria, on which we commented last week (January 19, p. 169), the corrected figures for which may be appreciably different from those we discussed.

Quarterly Return for Eire

In the third quarter of 1951 the infant mortality rate in Eire was 36, as compared with 37 for the third quarter of the previous year. The death rate per 1,000 from tuberculosis, with the corresponding figure for 1950 in parentheses, was as follows: all forms, 0.6 (0.7); respiratory system, 0.4 (0.5); all other forms, 0.2 (0.2). The number of deaths from influenza was 59, as compared with 30 in the third quarter of 1950.

Week Ending January 12

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,055; whooping-cough 2,394; diphtheria 33; measles 2,840; acute pneumonia 1,056; acute poliomyelitis 36; dysentery 315; paratyphoid fever 3; and typhoid fever 3.

Graphs of Infectious Diseases

The graphs below show the uncorrected numbers of cases of certain diseases notified weekly in England and Wales. Highest and lowest figures reported during the nine years 1942-50 are shown thus -----, the figures for 1951 and 1952 thus ———. Except for the curves showing notifications in 1951 and 1952, the graphs were prepared at the Department of Medical Statistics and Epidemiology, London School of Hygiene and Tropical Medicine.

Infectious Diseases

A general rise occurred in the notifications of infectious diseases in England and Wales during the week ending January 5. The largest increases were measles 1,160, whooping-cough 752, and acute pneumonia 295.

The notifications of scarlet fever were 7 more than in the preceding week; the largest local fluctuation was a decrease of 34 in Lancashire. The largest rises in the number of notifications of whooping-cough were Yorkshire West Riding 113, Warwickshire 93, and Staffordshire 69. The increased incidence in these counties was due to the experience of the county boroughs. The notifications of diphtheria were 2 more than in the preceding week. The chief features of the returns of diphtheria were decreases in Lancashire 9 and Lincolnshire 5. A rise in the incidence of measles was recorded throughout the country, although only 13 cases were notified in the five south-western counties and the incidence in London and the south-midland counties was relatively low. The largest rises in the notifications of measles were Lancashire 191, Warwickshire 152, Staffordshire 126, and Kent 90. The rise in acute pneumonia was general throughout the country; the largest increase was London 56.

The notifications of acute poliomyelitis increased by 1 for paralytic and by 4 for non-paralytic cases. The largest returns were Kent 4 and Lancashire 3.

A further 38 cases were notified from the outbreak of dysentery in Norfolk, Norwich C.B. The other large returns of dysentery were Middlesex 34, Lancashire 34, London 30, Devonshire 19, Yorkshire West Riding 14, and Northumberland 13.

The largest centre of food-poisoning during the week was Northamptonshire 119 (Towcester R.D. 39, Northampton C.B. 36, Brixworth R.D. 25).

Medical News

French Scholarships in Medical Science.—Under the terms of a reciprocal arrangement with the Centre National de la Recherche Scientifique, the Medical Research Council invites applications from British workers in medical science, excluding clinical medicine, for two scholarships tenable at research institutions in France during the academic year 1952-3. The scheme is intended for young graduates in medicine or science who have already had some experience in a branch of medical science. Candidates must be of British nationality and have at least a working knowledge of French. The stipend of the scholarships will ordinarily be within the range of 45,000-90,000 francs a month, according to qualifications and experience, and married

men will receive a supplementary allowance (payable in sterling by the Council); the grade appropriate to each individual will be decided by the C.N.R.S. in consultation with the Council. Provision will also be made for travelling expenses to and from the place of work. Forms of application may be obtained from the Secretary, Medical Research Council, 38, Old Queen Street, London, S.W.1, with whom applications must be lodged by March 31.

British Schools Exploring Society: 1952 Expedition.—Applications are invited for the posts of an honorary physician and an honorary surgeon for the Central Iceland expedition, leaving about July 28 and returning about September 16. The entire cost to each member will be £120, plus about £2 10s. for personal equipment. Applicants should apply as soon as possible to the secretary, British Schools Exploring Society, c/o Royal Empire Society, Northumberland Avenue, W.C.2.

South African Medical Research Fellowship.—Applications may be submitted for the 1952 award of the Eli Lilly medical research fellowship, from practitioners registered in South Africa. The closing date is May 8, and full details may be obtained from the honorary secretary of the selection committee, Capetown Postgraduate Medical Association, P.O. Box 2980, Capetown, South Africa.

John Hunter Commemoration Service.—A service will be held at St. Martin-in-the-Fields at 11 a.m. on Thursday, February 14, in commemoration of the fact that John Hunter's grave was in this church until 1859, when the remains were removed to Westminster Abbey. The discovery of the Hunter coffin was made by Frank Buckland, whose name is also commemorated on the plaque. The service will be taken by the Dean of Westminster. An address will be given by Sir Gordon Gordon-Taylor, the lesson read by Sir Cecil Wakeley, and the unveiling carried out by Sir Henry Dale.

Old Journals.—Readers who would like to help their colleagues abroad can do so by sending their used *British Medical Journals* and other medical periodicals to the Mailing Department of the British Council, (65, Davies Street, London, W.1). They should be marked "For Overseas Distribution," and will then be sent to those countries most in need of up-to-date medical literature. A number of free copies of various journals are being sent to libraries in Yugoslavia and elsewhere, but many more are needed.

Help in Establishing New Libraries.—The Department of Scientific and Industrial Research has recently helped the Association of Special Libraries and Information Bureaux to establish a consultant information service. This service, drawing upon the existing resources of Aslib, and backed by new research into information techniques, is now available to advise those who are considering the establishment of special libraries and information services in industry and research establishments, and to assist the development of existing services. Details of this service and other facilities can be obtained from the Director, Aslib, 4, Palace Gate, London, W.8.

Search for Silvester.—During the last few years several exhaustive but unsuccessful searches have been made for a portrait of Henry Robert Silvester (1828-1908), who first described his method of artificial respiration in the *Journal* in 1858. We should be glad to hear from any reader who may have knowledge of the existence of such a portrait.

British Association of Otolaryngologists.—At the annual general meeting of the British Association of Otolaryngologists held on December 7, 1951, the following were elected officers for 1951-2: *President*, Mr. V. E. Negus; *Vice-president*, Mr. F. C. W. Capps; *Honorary Secretary*, Mr. Myles L. Formby; *Honorary Treasurer*, Mr. W. A. Mill.

Medical Research Council.—The Earl of Limerick has been appointed a member of the Medical Research Council and will be its chairman, in succession to the late Viscount Addison.

Order of St. John of Jerusalem.—The name of Dr. J. Main Russell, who has been promoted to Officer (Brother) in the Venerable Order of the Hospital of St. John of Jerusalem, was omitted from the list of promotions in, and appointments to, the Order published in the *Journal* (January 19, p. 160).

Scottish Western Region Association of Psychiatrists.—At a general meeting of the association on November 16, 1951, the following office-bearers were elected for the year 1951-2: chairman, Professor T. Ferguson Rodger; vice-chairman, Dr. W. Mayer-Gross; secretary, Dr. J. F. McHarg (Glasgow Royal Mental Hospital); treasurer, Dr. J. Milne. All sections of psychiatry in the region have representatives on the committee.

Fine Arts at the Ministry of Health.—The 21st annual exhibition of the work of the Ministry of Health Art Club and Camera Club was opened at 23, Savile Row, W.1, on January 21 by the Minister of Health. About 30 exhibitors are showing over 40 oil paintings, the same number of water colours, pastels, and etchings, and some sculpture, as well as some beautiful photographs. The artists have mostly chosen landscapes as their subject, and there is a notable absence of abstract work or of "modern art." The standard is high, often comparable with the Royal Academy's summer show.

Emergency Bed Service: Applications and Admissions.—During the seven days ending January 21 the number of applications made by doctors to the London Emergency Bed Service for admission of patients was 1,061, of whom 83.12% were admitted. A white warning, indicating that the percentage of admissions fell to 82½, was issued on January 18 and cancelled on January 22.

COMING EVENTS

Hunterian Society.—The annual dinner will be held at the Savoy Hotel, Strand, W.C.2 (Embankment entrance), on Thursday, February 14, at 7 for 7.30 p.m. The price of the dinner is 30s. Acceptances and cheques should be sent to Mr. Alec W. Badenoch, 110, Harley Street, W.1, before February 11. If Fellows will state with whom they would like to sit, every effort will be made to meet their wishes.

Films in Teaching.—A combined meeting of the Royal Society of Medicine and the Scientific Film Association on "Recent Research on the Effectiveness of Films in Teaching" will be held at the Royal Society of Medicine, 1, Wimpole Street, W.1, at 8 p.m. on Friday, February 29. The opening speakers will be Professor Patrick Meredith, Dr. H. Ellis Lewis, and Mr. John Maddison.

Medical Artists' Association.—Drawings for the examination for membership should reach the chairman of the board of examiners, c/o Dr. Tompsett, Royal College of Surgeons, Lincoln's Inn Fields, London, W.C.2, not later than Thursday, February 28. Application forms will be sent on request by Miss Mary Hawker, Snowdrop Cottage, Slut's Lane, Lindfield, near Haywards Heath, Sussex.

Tuberculosis Educational Institute.—Intensive three-day clinical courses will be held at the following centres during 1952:

Cheshire Joint Sanatorium, Market Drayton, Shropshire, March 19, 20, and 21; May 14, 15, and 16; November 12, 13, and 14.

King George V Hospital for Diseases of the Chest, Godalming, Surrey, February 27, 28, and 29; June 4, 5, and 6; October 1, 2, and 3.

Red Cross Sanatoria of Scotland (Tor-na-Dee and Glen o' Dee), March 19, 20, and 21; May 21, 22, and 23; October 15, 16, and 17.

The fee for each course is three guineas, and applications should be sent to the secretary, Tuberculosis Educational Institute, Tavistock House North, Tavistock Square, London, W.C.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Monday

GRESHAM COLLEGE, Basinghall Street, London, E.C.—January 28, 5.30 p.m., "*The Physiology of the Brain—Sensations*," first of four lectures by Professor H. Hartridge, F.R.S. (See also January 29, 30, and 31.)
INSTITUTE OF PSYCHIATRY, Maudsley Hospital, Denmark Hill, London, S.E.—January 28, 5.30 p.m., lecture-demonstration for postgraduates by Dr. E. Stengel.
LONDON UNIVERSITY.—At Physiology Theatre, University College, Gower Street, W.C., January 28, 5.30 p.m., "*The Metabolism of Ethyl Alcohol*," Special University Lecture in Pharmacology by Dr. E. Jacobsen (Copenhagen University).
MANCHESTER MEDICAL SOCIETY: SECTION OF GENERAL PRACTICE.—At Physiology Theatre, Medical School, Manchester University, January 28, 9 p.m., "*The Soul of Medicine*," by Dr. G. J. Langley.
MANCHESTER MEDICAL SOCIETY: SECTION OF ODONTOLOGY.—At Lecture Room, Manchester Dental Hospital, January 28, 5 p.m., "*Anatomy for the Clinician*," by Professor R. J. Last.
MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—January 28, 8.30 p.m., "*Surgery of the Spleen and its Indications*," discussion to be introduced by Sir Lionel Whitby and Mr. Rodney Maingot.
ROYAL EYE HOSPITAL, St. George's Circus, Southwark, London, S.E.—January 28, 5 p.m., "*Ptoxis*," by Dr. T. H. Whittington.
UNIVERSITY COLLEGE, Physiology Theatre, Gower Street, London, W.C.—January 28, 5.30 p.m., "*The Metabolism of Ethyl Alcohol*," by Dr. Erik Jacobsen (University of Copenhagen).

Tuesday

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., January 29, 5.30 p.m., "*Carcinogenesis*," by Professor A. Haddow.
GRESHAM COLLEGE, Basinghall Street, London, E.C.—January 29, 5.30 p.m., "*The Physiology of the Brain—Movements*," second of four lectures by Professor H. Hartridge, F.R.S. (See also January 28, 30, and 31.)
●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—January 29, 5.30 p.m., "*Epithelioma*," by Dr. R. T. Brain.
MANCHESTER MEDICAL SOCIETY.—At Large Anatomy Theatre, Medical School, Manchester University, January 29, 4.30 p.m., "*Animal Electricity*," University Lecture on the History of Medicine by Professor W. Schlapp.
SOCIETY FOR THE STUDY OF ADDICTION.—At The Barnes Hall, Royal Society of Medicine, 1, Wimpole Street, London, W., January 29, 8 p.m., joint meeting with Medico-Legal Society. "*A New Form of Treatment for Delinquent Alcoholics as Applied in Denmark*" (Illustrated with Cinematograph Film), by Dr. Erik Jacobsen (Copenhagen). A discussion will follow.

Wednesday

EDINBURGH CLINICAL CLUB.—January 30, 4 p.m., clinical meeting by Miss G. Herzfeld. Visit to Bruntsfield Hospital.
GRESHAM COLLEGE, Basinghall Street, London, E.C.—January 30, 5.30 p.m., "*The Physiology of the Brain—The Special Senses*," third of four lectures by Professor H. Hartridge, F.R.S. (See also January 28, 29, and 31.)
●INSTITUTE OF DERMATOLOGY, Lisle Street, Leicester Square, London, W.C.—January 30, 5.30 p.m., "*Mycology—Sporotrichosis: Blastomycosis*," by Dr. R. W. Riddell.
INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., January 30, 4.30 for 5 p.m., "*Haematuria*," by Mr. A. W. Badenoch.
LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—At Royal Free Hospital School of Medicine, 8, Hunter Street, Brunswick Square, W.C., January 30, 8.30 p.m., "*Breast Feeding Without Dogma*," by Dr. Charlotte Naish.
ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW, 242, St. Vincent Street, Glasgow.—January 30, 5 p.m., "*The Treatment of the Typhus Fevers and Typhoid Fever with the Newer Antibiotics*," Dr. John Burns Lecture by Dr. Raymond Lewthwaite.

Thursday

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., January 31, 5.30 p.m., "*The Physiological Basis of Visual Sensation*," by Dr. L. C. Thomson.
EPSOM AND SUTTON INTER-HOSPITAL PSYCHIATRIC ASSOCIATION.—At Horton Hospital, Epsom, January 31, 5.30 p.m., clinical meeting. "*Some Problems in the Treatment of Neurosyphilis with Penicillin*," by Dr. M. Whelen; "*The Life Cycle of the Malaria Parasite*," film to be introduced by Mr. P. G. Shute; demonstration of cases by members of medical staff of Horton Hospital.
GLASGOW UNIVERSITY MEDICO-CHIRURGICAL SOCIETY, The Union, University Avenue, Glasgow.—January 31, 7.30 p.m., "*The Science and Art of Cardiology*," by Professor I. G. W. Hill.

Any Questions ?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Vitamins during Lactation

Q.—Do breast-fed infants get enough vitamins A and D in their mothers' milk? If so, does the amount of the vitamins in the milk vary according to the mother's vitamin level? Do the cod-liver oil tablets which mothers take protect them from vitamin depletion, or do they merely provide a surplus which can "spill" over into their milk?

A.—Breast-fed infants receive adequate vitamin A in their mothers' milk, but only marginal amounts of vitamin D. Under favourable circumstances the vitamin-D supplies are supplemented by direct exposure to sunlight. The amounts of the vitamins in breast milk do not vary much unless very massive doses are given to the mother. The cod-liver oil tablets protect the mothers from depletion in so far as they restore the heavy drain of vitamins which must be taken from their reserves.

Instruments in Spirit

Q.—Is there any way of treating surgical spirit, after it has been used for storing instruments and syringes in the surgery, so that it may be used again?

A.—The only really satisfactory method of purifying spirit is by distillation, but this is forbidden (except under licence) by the Methylated Spirits Regulations.

Traces of water can be removed from undiluted spirit by allowing it to stand over dry quick-lime (calcium oxide) or by adding potassium carbonate and decanting the clear supernatant fluid. The usual formulae for surgical spirit, however, contain castor oil, diethyl phthalate, and either naphtha or methyl salicylate in industrial methylated spirits. These substances may prevent a clear solution from being obtained by the above method. Also the most effective bactericidal strength of alcohol is 70 to 75%.

The Medical Research Council's *Memorandum No. 15* (H.M.S.O.) on "The Sterilization, Use, and Care of Syringes" approves of the use of alcohol for sterilizing syringes only when heat methods are not available. A technique is described using 70 to 75% alcohol. With instruments, again the best method is by heat, and this is recommended by the M.R.C. *Memorandum No. 11* (H.M.S.O.) on "The Control of Cross-Infection in Hospitals."

Strained Eyes

Q.—Is it possible through reading with a bad light, using ill-fitting spectacles, etc., to damage one's eyes, in the sense of producing permanent changes needing correction with lenses? The necessity for wearing spectacles is often ascribed by the laity to unwise "straining" of the eyes, particularly when young. Is there anything in this?

A.—The misuse of the eyes from working in bad light, wearing ill-fitting spectacles, and lenses not properly centred, etc., may have both general and local results. Headaches, loss of power of concentration—leading in children to bad school reports—mental fatigue, irritability, and mild indigestion may all be caused by eye-strain. Locally, ciliary spasm and local congestion and lenticular astigmatism may also be caused. These conditions are relieved by treatment, teaching of good ocular habits, and the proper adjustment of the correcting glasses. Apart from ciliary spasm and local congestion, which may be recalcitrant, the other conditions are not permanent.

Pepys; 11.30 a.m., "Allergy and A.C.T.H.," by Professor G. W. Pickering; 12 noon, discussion. Afternoon session: 2.30 p.m., "The Basis of Antihistamine Therapy," by Dr. B. Halpern; 3.15 p.m., "The Present Place of Antihistamine Therapy in Clinical Practice," by Dr. C. J. C. Britton; 4.45 p.m., business meeting.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

- Evans.—On January 14, 1952, at New Cross, London, S.E., to Alexa (formerly Mitchell), M.R.C.S., L.R.C.P., wife of Dr. C. J. Evans, a daughter—Mary.
- Tweedie.—On January 10, 1952, at Tripoli, Lebanon, to Gay, wife of G. C. Tweedie, M.B., F.R.C.S.Ed., a son—Thomas Cunningham.

DEATHS

- Gaskell.—On January 12, 1952, at Greenwood, Fareham, Hants, Sir Arthur Gaskell K.C.B., O.B.E., F.R.C.S., D.P.H., Surgeon Vice-Admiral, R.N., retired, aged 80.
- Mackinnon.—On January 12, 1952, at Craig-a-Charran, Portree, Skye, William Donald Mackinnon, M.B., Ch.B., D.P.H.

Herpes Gestationis

Q.—*I have this week seen a case of herpes gestationis. History: First pregnancy—appearance of typical rash at fourth month; despite treatment crops of vesicles persisted to the end of the pregnancy and then cleared up spontaneously. Second pregnancy—as above. Third pregnancy, now five months gone—herpes appeared at fourth month and is running the usual course. (1) Will you please suggest treatment? She did not have serum last time; would you recommend this, as everything else was tried without success? (2) What is the explanation of this syndrome?*

A.—Herpes gestationis is distinguished from other cases of dermatitis herpetiformis only by the fact that it occurs during pregnancy. The cause of dermatitis herpetiformis is unknown, and the virus theory of its origin is as yet unproved. It is not known why pregnancy should have this influence in some cases.

It is very doubtful whether serum or autohaemotherapy really affects the disease, and the treatment of the pregnant patient should be the same as for dermatitis herpetiformis in general. Most cases will eventually yield to the administration of arsenic or sulphapyridine, and it would be as well in this case to make sure that adequate dosage was given before the treatment was abandoned. Local treatment is purely symptomatic, for the relief of irritation and the prevention of secondary sepsis.

Carbon Dioxide Slush

Q.—*How is carbon dioxide acetone slush prepared? How is it used in the treatment of naevi?*

A.—For the preparation of carbon dioxide slush, acetone and carbon dioxide snow are required. The latter is most conveniently made in the consulting-room with a "Sparklet" apparatus; the carbon dioxide ice used in a refrigerating plant is not satisfactory. The powdered snow is placed in a gallipot and a few drops of acetone added. The mixture is stirred with a glass or wooden rod so as to make slush of suitable consistence. It is then best applied to the skin with a camel-hair brush or a thin wisp of cotton-wool.

Carbon dioxide slush has its chief use in the treatment of superficial haemangiomas. It is easier to apply to a large or irregularly shaped area than solid carbon dioxide, but it has a more superficial effect because pressure cannot be applied as it can with a pencil of snow. Most of the haemangiomas which respond to carbon dioxide freezing extend to a moderate depth and are better treated with solid snow. On the other hand, the more superficial lesions are less responsive to treatment, so that slush has a rather limited use.

Fluorescent Lighting

Q.—*In an engineer's drawing-office the draughtsmen require a very good light. Is there any medical reason why a fluorescent lamp should not be brought down from the ceiling to within a couple of feet (60 cm.) of the table?*

A.—There is no medical reason why a fluorescent lamp should not be mounted as low as 2 ft. above a draughtsman's table, provided the draughtsman cannot ordinarily see the lamp itself and so be subjected to glare. Many of these lamps are used as low as this for illuminating bench work in factories, but they are fitted with trough reflectors which allow the light to reach the working area but screen the bright lamps from the workers' view.

Post-herpetic Neuralgia

Q.—*What is the best treatment of post-herpetic neuralgia (T 6 on the left side)? I have a case in which there has been no response to analgesics, aneurin, mixed vitamin-B preparations, short-wave diathermy, or deep x-ray.*

A.—Treatment of established post-herpetic neuralgia, especially in an elderly patient, is frequently unrewarding. There are usually two elements in the condition: paraes-

thesiae consisting of numbness, tingling, sensations of "crawling," etc., which are a constant source of discomfort rather than a major disability and which do not generally respond to any form of treatment; the second element of severe pain is on the whole less common, and when present may be intractable to treatment but occasionally is relieved by a posterior rhizotomy of several roots or antero-lateral chordotomy.

NOTES AND COMMENTS

Gadgets for the Armless.—ANOTHER EXPERT writes: I have a simpler gadget for holding a telephone to the ear which your questioner ("Any Questions?" December 8, 1951, p. 1413) may find useful. It is made from a slab of hard rubber 2 cm. thick and measures 8 cm. across its longest diameter. The accompanying photograph shows its shape. It fits on to the handle of the

telephone, which rests comfortably on the shoulder against the ear and near the mouth. Not only the armless may find this useful. Personally, I find two hands are not enough, and with this gadget, after a little practice, two hands are left free for writing, etc. Provided it is placed about the middle of the handle of the telephone, it is comfortable to use, and at the same time does not affect the position of the receiver on its stand.

Correction.—An unfortunate error occurred in our report (January 12, p. 102) of the contribution by Dr. D. K. Briggs (American Hospital of Paris, Neuilly-sur-Seine) to the meeting of the General Practice Section of the Royal Society of Medicine, held on December 19. Lines 3 and 4 of the report of his remarks (p. 103) should read: "... treatment was determined on considerations less purely scientific than those obtaining in research centres."

INFLATION OF DOCTORS' LISTS

ACTION OF G.M.S. COMMITTEE

Many letters have been published in the *Supplement* and received at B.M.A. House concerning the action taken by executive councils in asking practitioners to help in tracing the whereabouts of "missing" patients. The background to these arrangements for reducing inflation is described below.

Soon after the appointed day the General Medical Services Committee became disturbed at the unevenness and apparent diminution of the capitation fee as between one area and another. The Committee's representatives on the Distribution Committee were satisfied that the proper amount for capitation fees went into the pool each quarter and that the whole pool was distributed. It was therefore clear that there must be internal factors which were causing the trouble.

Names on Several Lists

Following discussions with the Ministry of Health, it became evident that the major factor was the inflation of doctors' lists, and because of this inflation doctors were receiving capitation fees for persons who had died or were on the list of some other doctor in their own or another area. Indeed, many names were on the lists of several doctors. The Committee was, and still is, of the opinion that in order to get a fair distribution this inflation must be dealt with. It suggested as a long-term measure the establishment of a central register such as existed before the war. Unfortunately at that time, as a result of the war, the introduction of the new Service, and the shortage of clerical staff, it was impossible for the suggestion to be accepted, but a promise was given that action would be taken as soon as possible.

Subsequently the Committee was informed that the Ministry proposed to carry out a clearance of doctors' lists, and approval was sought for bringing this about. Such a scheme was necessarily difficult and complicated and placed much extra work on executive councils. Nevertheless, after further discussion and modifications to the original proposals, the Committee gave its approval to the plan. The detailed extensive and essential preliminary work has been going on for several months, but recently it has become evident that difficulties have arisen in dealing with the residual names. These difficulties were immediately brought to the notice of the Ministry, and a further discussion took place in which both sides endeavoured to find ways and means of eliminating many of the undesirable consequences of the plans.

Committee's Suggestions

The Committee for its part made the following suggestions:

- (1) That the period allowed for the final check-up on untraced names be considerably extended;
- (2) That executive councils should accept a doctor's assurance that a patient is living at a particular address, even though it had not been possible to obtain the identity number and make further inquiry themselves;
- (3) That the absence of an identity number would not of itself mean that a patient was removed from a doctor's list;
- (4) That executive councils should send a second explanatory letter to patients who, despite past efforts, are still untraced;
- (5) That executive councils should give doctors individual notices of the final residue of untraced names;
- (6) That doctors should not be expected to pay personal visits in order to trace the whereabouts of missing patients, but rather that this task should fall upon a representative of the executive council.

The Ministry is now considering all these points, and has undertaken to issue further instructions to executive councils in the very near future. After the discussion at which these suggestions were made an agreed statement was sent to the Press and published in the next issue of the *Supplement* (December 29, 1951, p. 289).

Higher Capitation Fee

It should be emphasized that the "clearance of lists" will not, and cannot, result in a smaller pool. It is the inflation which is responsible for the diminished and unequal capitation fee. The elimination of duplicated names will, however, result in a "truer" capitation fee—a higher one. Had every doctor's list been inflated to the same extent, the actual total amount would be the same for a smaller number on his list. Unfortunately, it is apparent that some lists, especially in some areas, are more inflated than others, and this has given rise to substantial variations in the capitation fee.

The Committee is therefore satisfied that in the long run practitioners will benefit from the clearance of lists, and that it is in their interests to give executive councils all reasonable help. It is hoped that, as a result of the action outlined above, this end will be achieved without the inconvenience and burden of work which had emerged from the original plan.

The Ministry has already agreed to extend the period allowed for the final check on untraced names, and the contents of the new E.C.L. (circular letter) giving effect to changes in the present arrangements will be published in these columns as soon as it is available.

GENERAL PRACTITIONERS' REMUNERATION

COUNSEL TO MEET ADJUDICATOR

The respective counsel of both sides will meet Mr. Justice Danckwerts on January 30, to discuss the procedure for the hearing of the general practitioners' remuneration claim. As previously announced, Mr. Justice Danckwerts is the adjudicator appointed to hear this claim.

CO-OPERATION IN THE N.H.S.

SHEFFIELD SCHEME

Lack of co-ordination between local health authority, regional hospital board, and executive council is one of the defects of the Health Service. To try to overcome it the Sheffield Regional Hospital Board has formed medical co-ordinating committees in its six main hospital areas. Within each area each local health authority is represented by the medical officer of health, each hospital management committee by a consultant, and each local medical committee by two general practitioners. The committees vary in size between 8 and 21 members.

The senior administrative medical officer attended the first meeting of each committee, and a number of problems have been suggested for discussion. These include the employment of general practitioners in hospitals, the provision of maternity beds for general practitioners, the care of patients at home in co-operation with hospital staff, and the division of responsibility between general practitioner and consultant for patients awaiting admission to tuberculosis sanatoria. Also to be discussed are many questions on the relations between the hospitals and the local authority.

Discussions have already begun in these committees, and they are expected to be of much help in increasing liaison between the three main branches of the Health Service.

MATERNITY INSURANCE BENEFITS

MORE CASH FOR BIRTH AT HOME

The mother who has her baby at home should get a higher cash maternity benefit than the mother who is confined in a National Health Service hospital, recommends the National Insurance Advisory Committee (chairman, Sir Will Spens). Its report on *Maternity Benefits* (H.M.S.O., 1s. 3d.) has not yet been considered by the Government. The changes suggested in it would need an amending Act of Parliament before they could come into effect.

Recommending that the mother confined at home should get a higher benefit, the committee says that some women now try to have their confinement in a Health Service hospital solely to save money. The committee received many representations in favour of this change during its investigation. As to the extra cost of home confinement, the committee heard evidence that it might be as low as £2 or might be anything between £6 and £10. It agreed that a reasonable minimum figure would be £3, and decided not to make an exception for the woman confined in hospital who already has children at home. Commenting on this decision, the committee says: "A decisive factor appears to us to be that the sum of £3, as a differential between the costs of the two confinements, is relatively so small as not to justify the insertion of an intermediate figure."

The present maternity grant (£4) and attendance allowance (£1 a week for four weeks) should be replaced by a prenatal grant of £4 and a maternity grant, to be paid after confinement, of £6 for confinements at home and £3 for confinements in hospital. The prenatal grant should not be paid more than eight or nine weeks before the expected confinement. The post-natal grant for home confinements should be paid in two instalments—£3 immediately after confinement, and a further £3 two weeks after confinement. For hospital confinements £3 should be paid two weeks after confinement.

The Maternity Allowance

A woman who ordinarily goes out to work can get a maternity allowance in the weeks before and after her baby is born. At present the allowance can be claimed by a working woman although after her marriage she stopped paying her National Insurance contributions. The committee recommends that maternity allowance should in future be given only when the necessary contributions have been paid. Among other changes, it also recommends that maternity allowances should be available for 18 weeks instead of 13 weeks, but at 26s. instead of the present 36s. a week. Payment would begin 11 weeks before the baby was expected.

EXCEPTIONAL CONSULTATIONS

Under para. 6 of the Terms and Conditions of Service consultants who have no contract with the regional hospital board but who are called in exceptionally to hospitals or clinics for a special visit (because of their unusual experience or interest) are paid at the rate of five guineas a visit.

The staff side of Whitley Committee B has for some time been trying to alter this so that the fee should be paid for occasional and exceptional consultations outside consultants' normal duties whether or not they have a contract with the board concerned.

Problem of Scarcity

In putting forward this proposal the staff side has been thinking chiefly of consultants in neurosurgery and plastic and thoracic surgery. Consultants in these specialties are few in number and are therefore often in contract with a number of boards, so they frequently have to travel considerable distances for a consultation outside their normal duties. Yet they cannot receive a fee under para. 6 unless the consultation is outside the area of the regional board or boards with which they are in contract. In addition, these consultants, because of their scarcity, normally hold contracts for the maximum number of sessions, and are therefore unable to adjust the number of sessions to overcome the difficulty.

The management side has not agreed to a change, arguing that to do so would be a departure from the principle that the consultant's contract must cover all duties to the board except domiciliary consultations.

Suggested Solution

In the course of the negotiations the management side indicated that, if any consultant in these specialties is overburdened, one solution would be for him to advise his regional board that he is unable properly to fulfil all the duties laid upon him, so that the board will have to consider an additional appointment.

At its last meeting the staff side decided to acquaint consultants in these specialties with the position and call their attention to the management side's statement.

B.M.A. FILM COMMITTEE

At a meeting of the Film Committee held at the end of 1951 the final arrangements for the publication of the catalogue of films in the Library were approved, and the catalogue, which was reviewed in the *Journal* of January 19 (p. 152), has now been published.

A full discussion took place on the teaching value of a medical film, and it is proposed to prepare, and have published if possible, a report of the Committee's views on the subject.

The Committee has been active in appraising medical films which have come to its notice, and the views of the appraisal panels have been recorded to assist inquirers.

A representative has been appointed to serve on the sub-committee of the British Standards Institution, which is considering the preparation of a British Standard for containers for filmstrips.

REGISTRARS GROUP OF THE B.M.A.

The Association's Registrars Group has become increasingly active during the past year in promoting and protecting the professional interests of hospital registrars. The Group Council, which comprises three representatives (teaching and non-teaching) of each regional Registrars Group, met three times during 1951, and the Executive Committee of the Group Council met four times.

Among the many subjects considered, the most important was the discussions between the profession and the Ministry of Health on registrar establishments. On two occasions representatives of the Group have met and discussed this subject with the Joint Committee of the Royal Colleges, which negotiates with the Government on matters concerning hospital medical staffs.

Join the Group

Machinery is fully established whereby the views of the Registrars Group may be submitted to the Central Consultants and Specialists Committee and thence to the Joint Committee. Members of the B.M.A. in the registrar grades who have not yet joined the Group are urged to complete the application form below and send it to the Secretary of the Association; and also to participate in the regional activities of the Group, so that the regional representatives on the Group Council may be fully apprised of the views of those they represent.

BRITISH MEDICAL ASSOCIATION REGISTRARS GROUP

Form of Application for Membership

To the Secretary,
British Medical Association,
B.M.A. House,
Tavistock Square,
London, W.C.1.

I wish to apply for membership of the Registrars Group of the Association, and understand that the inclusion of any individual member within the Group is at the discretion of the Group Council subject to appeal to the Council of the Association.

I am a member of the Association, and am engaged as a hospital registrar.

EXCHANGE VISITS WITH CANADA AND U.S.A.

The scheme initiated last year, with the approval of the Bank of England, for exchange visits between members of the American, British, and Canadian Medical Associations will be continued this year.

Exchanges with Canada: Two doctors from Britain may visit Canada in exchange for two doctors from Canada. Each doctor from Britain will be required to make all his own travel arrangements and to deposit up to £200 with the B.M.A. in London. On arrival in Canada he will be met by a representative of the Canadian Medical Association,

who will present him with the equivalent in Canadian dollars. Similarly, each Canadian doctor on arrival in Britain will be met by a representative of the B.M.A., who will present him with the sum deposited in sterling.

Exchanges with the U.S.A.: Three doctors from Britain may visit the U.S.A. in exchange for three doctors from the U.S.A. Each doctor from Britain will be required to make all his own travel arrangements and to deposit up to £200 with the B.M.A. in London. On arrival in the U.S.A. he will be met by a representative of the Medical Society of the State of New York, who will present him with the equivalent in U.S. dollars. Similarly, each U.S. doctor on arrival in Britain will be met by a representative of the B.M.A., who will present him with the sum deposited in sterling.

The duration of the visits is left to the discretion of the doctors concerned. The American, British, and Canadian Medical Associations cannot accept any responsibility for a doctor who allows his visit to outlast the money placed at his disposal.

Applications are invited from members of the B.M.A. to take part in such exchanges in 1952. Each applicant must state the object of his visit. Medical practitioners in all branches of the profession, including general practice and public health, are eligible. Applicants should also give approximate dates of the visit desired. (Successful applicants will in due course be required to give exact dates and details of travel.) Applications must be received by the Secretary of the B.M.A. by March 1.

GENERAL MEDICAL SERVICES COMMITTEE PREPARATIONS FOR THE ADJUDICATION

An all-day meeting of the General Medical Services Committee was held at B.M.A. House, London, on January 17, with Dr. S. WAND in the chair. The Committee decided in future to meet half an hour earlier in the morning.

It was reported that the Association had received invitations to submit nominations to the Minister for filling vacancies on the advisory committees of the Central Health Services Council. The Committee agreed unanimously that Dr. Wand's name should go forward to the Council for the Medical Advisory Committee as representing general practitioners.

A report on the preparation of the case to be presented to the adjudicator in the forthcoming remuneration inquiry was made. Discussions had taken place with counsel, and a meeting with Mr. Justice Danckwerts was taking place on January 30 to discuss procedure for the hearing. A point to be decided by the adjudicator was whether the hearing should be in private or public. The feeling of those immediately concerned was in favour of a public hearing save when any particular organization did not wish its remuneration figures to be disclosed. A request was made for practitioners, outside the membership of the Committee, who, having solid experience of practice, might be prepared to offer evidence.

Inflation of Lists

The SECRETARY of the Committee (Dr. D. P. Stevenson) read a statement on this subject (see p. 27). There were objections from some quarters in the Committee that the amount of inflation did not justify the trouble which would be incurred by doctors in effecting clearance of their lists, and that the true answer to the problem was that medical cards should be the criterion of treatment. The CHAIRMAN replied that, while they knew they could not get absolute clearance, the lists should be made as clear as possible, and future entries controlled from the central register.

A letter from the Liverpool Local Medical Committee was read transmitting a resolution passed at a meeting of general practitioners in Liverpool on January 6 protesting at the inadequacy of the moneys allocated to the Liverpool

Executive Council, which provided a capitation fee of only a fraction over 3s. 11d. for the last quarter, and calling upon the Minister to implement the promise made by his predecessor in 1948 of a capitation fee of 17s. 5d. per annum. Dr. GIBBONS, of Liverpool, said that his area was witnessing a steady decline in the capitation fee.

The SECRETARY of the Committee pointed out that the Distribution Committee was a Government committee on which they were represented, and the representatives had to abide by certain principles. If they were asked to treat certain information as confidential they must do so. While there was inflation of lists some areas would continue to get too small a slice of the national cake.

The Committee was reminded that out of the 17s. 5d. which was mentioned had to come basic salaries and emergency and anaesthetic fees. The 17s. 5d. might be the right amount, but it varied from area to area according to the extent of the inflation. The Registrar-General had asked that the quarterly population figures prepared by his department should be regarded as confidential to the Distribution Committee.

It was agreed, on the proposition of the CHAIRMAN, that, in view of the variations which existed, representations should be made to the Distribution Committee that the distribution figures should be available to the G.M.S. Committee.

During the discussion it was suggested that doctors who were purging their lists were penalized by the removal of names, whereas doctors who took no action were receiving payments to which they were not strictly entitled. It was agreed that this point should be put to the Ministry.

One suggestion was that the electoral roll in every area should be used as an additional method of tracing patients. Another, that every doctor should have the right to request that an official of the local executive council should go through the list with him. This suggestion also was accepted and a deputation for the Ministry was appointed.

Filling of Vacancies

The special subcommittee appointed at the previous meeting to consider alternative methods of dealing with the problem of the occupation of a deceased doctor's house in connexion with the filling of vacancies had not yet completed its work, but promised a report for the next meeting. It was stated that the East Midland Regional Medical Committee had expressed its disagreement with the proposals made by the G.M.S. Committee at the last Annual Conference concerning the filling of vacancies, and had asked that further action be deferred until the views of local medical committees had been obtained, and communications had been received from certain local medical committees supporting this view. The CHAIRMAN deprecated the practice of this circulation of proposals before anybody centrally had had an opportunity of considering them. If it continued it would mean that the work of the G.M.S. Committee would go by the board. The effect would be that decisions would be made at the periphery in the absence of full information. Dr. A. C. E. BREACH said there was surely no objection to local committees approaching other local committees.

After some further discussion it was decided to point out to local medical committees that the G.M.S. Committee was under an obligation to report to the Conference on this subject, and would do so fully.

The question of filling vacancies was also the subject of a statement from the management committee of the Executive Councils Association, which, before reaching a decision, had decided to obtain the views of the B.M.A. on the matter. This matter was deferred to the next meeting, and it was agreed that Dr. W. E. Dornan, chairman of the Medical Practices Committee, should be invited to be present.

Dispensing Capitation Fee

A lengthy report was made on a large number of matters, including the machinery for appeals by practitioners against

discontinuance of payment of basic salary, the medical treatment of lighthouse staffs and merchant seamen, medical service committee procedure, and maternity medical services, which had been discussed between representatives of the Committee and officers of the Ministry of Health. One of these matters concerned the case for a substantial increase in the dispensing capitation fee. The reply of the Ministry's representatives was that discussion on this question was barred for the moment because it was intimately bound up with the forthcoming adjudication on the general matter of remuneration. Deep dissatisfaction had been expressed at the lack of progress in this matter.

Dr. D. T. McDONALD said that figures in his area, Northumberland, indicated that dispensing doctors, who were getting 6s. 6d., were actually losing money. At the end of 1950 he had worked out the costs in his own practice and found that a loss was being incurred, but, hoping that something would be done to rectify the position centrally, he did not transfer to the tariff method. In 1951, in a practice with a list of 4,500, with dispensing done for 98% of the patients, the net loss was £200. The doctors were providing for the patients a chemists' service—the kind of service that chemists gave to prescribed-for patients, and by which they earned a reasonable living—and were incurring a loss in doing so. If the Ministry would not increase the dispensing fee, the only solution was to go on to the tariff.

This view was supported by Dr. KILLICK, chairman of the Rural Practitioners Subcommittee, who said that the Ministry had gone back on its promise. Doctors in rural districts were providing a service which the chemists were not providing. It was a 24-hour service, and it was given in areas where chemists did not think it economic to set up in business. Yet doctors were paid less than half the sum that the chemists were paid.

Dr. TALBOT ROGERS, who was one of those who went to the Ministry on this and other subjects, said that the officers of the Ministry were on weak ground, and he was surprised when it was suggested that it would be necessary to consult the Ministry's legal adviser in order to see whether it was possible to proceed any further in this matter at the present time without prejudicing the case which the Ministry would put before the adjudicator.

It was agreed that the Secretary should send a letter to the Ministry expressing the disappointment and frustration which were felt at the delay and lack of understanding which the Ministry had displayed in this matter, and intimating that failing an early and satisfactory reply rural practitioners would be advised to consider going over to the tariff system.

As to the relation of this matter to the forthcoming adjudication, the CHAIRMAN said that the proper course of action would be for the department and the Committee to work out together what would be an adequate dispensing capitation fee and then to let the adjudicator decide whether such a fee should be regarded as part of the total remuneration of general practitioners.

Reinstatement of Demobilized Personnel

The Committee considered a proposal for a scheme of automatic reinstatement of demobilized ex-Service men and women on doctors' lists. The opinion of the officers of the Ministry was that in view of the comparatively small size of this problem the introduction of such a scheme as had been suggested by the Committee, involving the use of food office machinery, would not be justified. They thought the position might be met by the revision of the present Form E.C.13. This proposal was agreed to, somewhat reluctantly, as an interim measure, but the matter is to be discussed further. Dr. HOWIE WOOD pointed out that as all demobilized personnel had to go to the food office for their documents there seemed to be no reason why, when doing so, they should not receive a medical card. A suggestion was that the food offices should be asked to let executive councils know the names and addresses of people who took out

ration books after demobilization, and that a medical card should then be supplied to such persons by the councils.

Association with Hospital Work

The Committee again spent some time on the question of the association of the general practitioner with hospital work. It was pointed out that, in addition to the special committee set up by the Council to consider and report upon the matter, the Working Party was considering it, and the Amending Acts Committee was in due course to consider the position of the general practitioner who wanted to become a consultant; in fact there were at least five committees engaged on this question or certain aspects of it. The CHAIRMAN suggested that when the adjudication was out of the way the next major problem to be tackled by the G.M.S. Committee should be the status of the general practitioner including his relation to hospitals. In the meantime the Committee had before it a useful memorandum prepared by one of its members, Dr. FRANK GRAY.

Among other business on the agenda were questions raised by various local medical committees or referred by other committees of the Association, and a memorandum by Dr. W. WOOLLEY on limited lists affecting institutions.

Heard at Headquarters

Child Guidance and its Results

A large conference of workers in child guidance clinics from all parts of the country, under the auspices of the National Association for Mental Health, assembled in London recently to hear reports on a follow-up of children who have passed through the clinics. At Bristol, for instance, of 338 children who attended the clinic in 1946, complete follow-up records have just been made of 202; but a psychiatric worker from the East London Child Guidance Clinic brought forward 45 cases of ex-clinic children who had been followed up twenty years after they left the clinic. Many of them were found to have made apparently stable marriages, but sometimes it was noted that the same faults and maladjustments appeared in their offspring, though in a milder degree, as had previously appeared in the parents. Two of the children had gained university degrees, another a high military award for conspicuous bravery in the war, others were in successful business careers or in highly skilled craftsmanship, and one was himself a teacher of maladjusted children. The reports on the follow-up were encouraging on the whole. The conference listened to an address by Dr. Alice Stewart, director of the Institute of Social Medicine at Oxford, who made a brilliant justification of this new, or newly entitled, specialty, in particular for its value in elucidating the remoter causes of disease.

Sir Wilson Jameson

Retirement has not diminished the pointedness of Sir Wilson Jameson's speech and pen, and his Stephen Paget Memorial Lecture, delivered before the Research Defence Society last November, was a masterly exposition of the history and present state of research. This was the twentieth lecture of the series, which began in 1927, the year after Stephen Paget's death. Sir Wilson Jameson spoke in particular of the strength of the partnership between research and administration as a result of the last war, and said that although the outlook was not all plain sailing they could be hopeful of the future. What was needed now was a peaceful period in which to apply their gains and use their ever increasing knowledge for the benefit of mankind. Immediately after his lecture Sir Wilson Jameson was elected chairman of the Society in succession to Professor A. V. Hill, who has held the chairmanship for ten years. Professor Hill recalled that 25 years ago he and Sir Wilson Jameson were co-operating in Hornsey in an effort to prevent

diphtheria among schoolchildren; but another speaker, Dr. Andrew Topping, recalled a still earlier association, dating back to 44 years ago, when he and Sir Wilson Jameson were students at Aberdeen.

Passion for Certification

Discussing how the sickness wages bill of co-operative societies might be reduced, a writer in the *Co-operative News* of January 19 feels that the great bulk of sickness claims, and especially those for long-period sickness, are genuine and in no way exaggerated. But what will startle doctors is his assertion that the only thing that will prune the bill "will be a change of heart on the part of the medical profession, whose passion for certification is the background cause of much unneeded absence." The writer seems to have fallen into the popular habit of finding, not a background cause, whatever that may be, but a scapegoat.

A Representatives' Hansard

The proposal to have a *Hansard* of Representative Meetings has been turned down on the ground of economy, for verbatim recording—which means the recording of every syllable uttered—is a costly business. One representative at the recent Special Representative Meeting, when the matter was discussed, suggested that the Association should purchase a mechanical recording machine, which would entail a certain capital outlay, but would be cheaper in the end than the employment of verbatim note-takers. He appeared to overlook the fact, however, that even after speeches have been "taken down," whether by the pen or the machine, they remain to be transcribed, and the transcription takes three or four times as long as the taking of the original note, and is really the costliest part of the business. Moreover, even when a mechanical recorder is used, a careful check has to be maintained concerning names, interjections, and all the accessory business of the meeting which would be lost on a blind record, and the transcription itself, without memory to assist the transcriber, may be very difficult and time-taking. The Representative Meeting must await more prosperous times for its *Hansard*.

Penny for His Thoughts

Last September an agreement between the Minister of Health and pharmacists was reached whereby an additional "on-cost payment and dispensing fee" became payable. A chiropodist writes to tell us that his executive council found that a dispensing fee was payable to him under this agreement. It covered one prescription, and the additional sum was sent by the council—a cheque for "One Penny Only."

Clearing the Flue

A distracted doctor, asking whether it is the Health Service that is abused or the general practitioner, sends us the following note "as one example of many" dropped in at his surgery: "Doctor, Will you please send Jack bandages lint cotton wool ointment. Bottle of medicine for Mrs. Smith for gastric flue. Tablets for headache."

Request from French Doctor

A French doctor living in Vichy would like his 21-year-old daughter to come to England in the spring to live with an English medical family for six months in return for some work, such as looking after children. Anyone interested should get in touch with Dr. H. A. Sandiford, International Medical Visitors Bureau, B.M.A. House, Tavistock Square, London, W.C.1.

Dangerous Drugs Act: Withdrawal of Authority

The Home Office announces that Dr. Terence O'Neil Fraser Kelly, (Aberdeen) is no longer authorized to be in possession of or to prescribe those drugs to which the Dangerous Drugs Regulations apply.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Rent at Health Centres

SIR,—It appears that all medical practitioners who work at a health centre will be charged a rental in the region of £350 per annum for the privilege of doing so.

We are already grossly underpaid. Although it is a nuisance having our surgery premises as part of our residence, it has its compensations financially, as we can obtain a certain amount of income-tax relief, which to some extent helps us with the upkeep of our unnecessarily large houses. Having to pay a rental for working at a health centre will therefore hit a lot of doctors with a left as well as a right.

Members of the medical profession who already work in Ministry of Health buildings are the medical and surgical specialists employed by the various hospital boards. What rental do these specialists pay towards the upkeep of their out-patient clinics with their attendant staffs of porters, nurses, and secretaries? I have a feeling they pay nothing. If this is so, why should their poor relations be asked to pay?—I am, etc.,

Leeds.

J. F. ROBINSON.

Help Now

SIR,—I have read with interest Mr. Donald M. O'Connor's letter (*Supplement*, January 12, p. 15) and the footnote by the B.M.A. Secretary, which misses the essential point, kept to the end by Mr. O'Connor for emphasis—"We want help now." I am encouraged by his letter to express my views in the hope that you will publish them, although I have for long now realized that there are only a minority of general practitioners, similarly placed to myself, who are likely to agree with me. I believe this minority is growing and has done so rapidly during the last year.

Being one of those severely hit financially by the N.H.S., and being one of the few, locally, who spoke at meetings prior to the appointed day, pointing out the danger of leaving the financial side of negotiations in the air, I have followed the subsequent conduct of our case with detailed interest, and have always admitted in my own mind that such conduct has been patient, reasonable, and dignified, as one would consider worthy of an honourable profession. This, however, does not prevent me from stating now that I consider our financial affairs have been brought to a state of nightmare craziness unsurpassed by anything imagined by W. S. Gilbert.

What other body, trade or professional, when it had successfully, though tardily, won the case for arbitration, would meekly accept quarter by quarter a dwindling remuneration, and at the same time set to patiently to revise errors and omissions made by the defunct Insurance Committee, with no compensation for time wasted?

If one agreed with our leaders in their negotiations, it is yet possible to say that one has now realized at what stage they went wrong. It is obvious that some error has been made or we should not still be meekly waiting after nearly four years. I am confident that the point where we failed was when Mr. Bevan, then Minister of Health, quite gently but cleverly manoeuvred us into a position where, to save public opinion, we were forced to state that under no circumstances should we strike. It was obviously right to make this statement, but having done so we should have at once refused to negotiate further until it was admitted by Government and people that, because we have no right to strike, arbitration must always be immediate and speedy, and the results of such arbitration carried out without delay.

Adjudication has been set in train and we must wait patiently for the judgment. On paper we have a good

case, as we have indeed had for the last six years, but I think Mr. O'Connor and some others would join me in believing that, even with a supremely favourable judgment, it is unlikely that we shall receive any additional hard currency before January, 1953, at the earliest.

I suggest, therefore, that it is not too late to make our point that the Minister of Health be informed that both sides, Government and profession, have lost sight of the fact that we alone of all professions have no right to strike and no taste for the use of force, and that not only are we absolutely indispensable but also that we have carried a superhuman burden, because we believe in the Health Service and the future of Medicine. Therefore, with some of us at breaking point, we should be given urgent consideration.

Secondly, I suggest that one of our fairly numerous medical M.P.s—and there are those with a gift of oratory who owe us a duty—should be persuaded to take a motion to the effect that "this House is deeply grateful for the patience and endurance displayed by our general practitioners, and is greatly encouraged by the success of our Health Service, of which their good will is the keystone, and is therefore determined that no time shall be lost in correcting the grave injustice done to them, so that the Service may develop and flourish as originally planned."

Finally, may I say, Sir, that as it seems highly unlikely that my suggestions will be adopted by any official body I intend to get as near as possible to carrying them out myself with whatever support I can rally?—I am, etc.,

Ockbrook, Derbyshire.

JAMES W. SMITH.

Tracing Patients

SIR,—The following communication was submitted by Dr. C. H. Ross Carmichael to a meeting of general medical practitioners held in Liverpool on January 6, and had the backing of all present:

"We are gravely concerned by the recent measures directed against inflation of lists, though we are all agreed that inflation is undesirable and that a proper remedy should be found. What specially disturbs us is the method by which it is proposed to delete names from our lists. Not only can we see that it is valueless as a guide to names genuinely calling for deletion, but we seriously question whether it is well founded in law. Patients duly registered with us are to be treated, for the purpose of remuneration, as if they were no longer on our lists, for no better reason than that they have failed to reply to a communication.

"We are told that we can only obtain relief by ourselves pursuing investigations that are strictly administrative, yet in very many cases there is no reason why we should fare better than the executive councils, and often there are reasons why we might fare worse. The manifest inequity of all this is especially alarming because it directly involves the one solid foundation on which our economic security is built—namely, the actual lists of persons for whom we are individually responsible. We cannot exaggerate the importance which we attach to any measures calculated to disturb these lists unfairly or otherwise improperly, and we take unqualified exception to the recent measures on all counts. We hold that the situation demands a 'stay of execution' pending further consultation between the Ministry and the B.M.A."

—I am, etc.,

Liverpool.

T. A. JERMY,

Hon. Secretary.

Liverpool Local Medical Committee.

SIR,—It is to be regretted that busy general practitioners should be asked to trace their patients on behalf of the executive councils. All this would appear to be quite unnecessary. The appropriate action to secure the names and addresses of the population in any area is for the records of the local food office to be made available to the executive council.

A refinement which would give completely accurate information is for the food office to be empowered to ask of all persons being issued with ration books the name of the doctor with whom they are registered. This may appear to some to savour of bureaucracy, but both food control and

the National Health Service are Government organizations, and to pass on information of this type would not be improper.—I am, etc.,

Brighton.

W. S. PARKER.

SIR,—Like others, I have had a list of "untraceable patients," 60% of whom had merely changed their address locally. I think there are two serious points to consider. First, the executive councils appear to have no machinery for keeping track of the patients on their lists other than naively expecting the public to keep them informed. As most people have to eat, liaison with the Ministry of Food would solve their difficulties.

Secondly, while I do not mind helping them out as an act of courtesy, I strongly object to doing it under threat. In effect, the executive council say: We haven't a clue where these people are, and we are going to make the doctors find out for us under penalty of financial loss. It simply is not good enough. Can someone teach these people manners?—I am, etc.,

Ashted, Surrey.

W. EDWARDS.

Time to Instruct Counsel

SIR,—Mr. Donald M. O'Connor (*Supplement*, January 12, p. 15) always puts first things first. He is impatient that at this late hour our leaders coolly tell us that before our long-awaited claim be heard they will have to instruct counsel and this will take some months. The Secretary of the B.M.A. found it necessary to answer this letter in a footnote, which in effect said that conditions are continually changing and evidence based on the cost of living must be submitted from a current date.

A glance through almost any issue of the *Economist* or the *Financial Times* would let the Secretary know that by the time these weeks or months have passed circumstances will have again changed, and against us all too, as the purchasing power of the pound diminishes further. Then presumably the expert witnesses to be called in our favour will have to start all over again gathering fresh evidence—thus more delay.

One would prefer rather to present the picture of our invidious position with a few bold strokes without nearly so much detail. The present position of our once dignified and financially comfortable profession is sufficiently obvious to the learned judge without a mass of detailed figures.

It is hard not to be attracted by the way the firemen handled their pay-claim dispute a couple of weeks ago. These very practical men merely omitted to keep themselves and their fire stations tidy for a few days. The result—their arbitration is already taking place.

If, as is at least a possibility, Mr. Butler, the Chancellor of the Exchequer, at the end of January puts a complete stop to wage increases, our goose will be cooked; we will be condemned to shabbiness and penury for years; our long-awaited graduated capitation rate will not materialize; the downtrodden assistants will continue to be exploited; and I for one will bitterly resent the fact that our representatives did not long ago make our profession stronger by taking upon themselves some compulsive powers to bring the weaker vessels into a strike, a lock-out, a rebellion, or whatever you like to call it, so that our just demands be met.—I am, etc.,

Dungannon, N. Ireland.

CONN McCLUSKEY.

Compulsory Retirement

SIR,—The *Supplement* of November 17, 1951, has just reached me, and I would refer to two letters by Drs. I. B. Barclay and H. Fisher (p. 221) on "Compulsory Retirement in Hospital Service." I would like to draw attention to another anomaly of this subject. I was retired at 65 last July after 25 years' service as radiologist at the same hospital. At the time of the appointed day, July 5, 1948, I was still paying £250 p.a. premiums for endowment assurances. I applied to contract out of the superannuation

scheme, but was refused permission, as it was not applicable to part-time specialists.

When this policy was reversed over a year later, as my policies would soon become payable I did not trouble to contract out. I failed to realize that, although my pay-slips from that time showed the 8% Government contribution to superannuation, this contribution was only actually payable to those who contracted out.

There may only be a few whom this affects, but it surely is an injustice which should be righted and made retrospective to August 1, 1949. It was useless to complain, as the regulations if read carefully make it plain, but it nevertheless is an injustice. Why should those who contract out be treated better than those who do not? I may add that up to a recent date (and I believe up to now) no one had been appointed to replace me, which, of course, is an economy in the medical service. I have been fortunate enough to obtain an opening in Kenya in spite of age.—I am, etc.,

P.O. Box 240 Nakuru,
Kenya Colony.

A. A. GREENWOOD.

SIR,—In the *Journal* of January 5 (p. 38) you have an annotation on "Compulsory Retirement." I should like to draw your attention to several facts:

(1) I am in full sympathy with the pathologists and radiologists but consider that they have no specific reason to be treated differently from general surgeons who are in a similar position.

(2) I have been refused point blank any honorary contract—no permission to treat patients in a pay-bed of a hospital in which one has served for 29 years and no domiciliary consultations, thus being cut off from the general practitioners who have used one for this purpose for years.

(3) No pension, though I raised this question originally at the S.E. Metropolitan Consultants Committee some two years ago.

(4) Do the B.M.A. really know how badly we are being treated? Do they really feel satisfied with the present method of filling the vacancies? If so, they are the only people who are.

(5) I have been a member for 40 years and remain one still hoping that some of these wrongs may be righted.

—I am, etc.,

Eastbourne.

E. WILSON HALL.

POINTS FROM LETTERS

Time to Instruct Counsel

MR. DONALD M. O'CONNOR (Launceston, Cornwall) writes: If I am permitted to comment on the Secretary's footnote to my letter (*Supplement*, January 12, p. 15) I would suggest that the words, "some little time," do not convey to the average reader quite the same idea as "several months" (*Journal*, November 10, 1951, p. 1141). Are the important relevant facts so deeply hidden that a team of expert witnesses would need long to learn them? Last week's *Economist* informs us that the index of wage rates rose by about 10% during 1951 and that the rise in prices was 12% in the same year. . . . A Government White Paper issued last year showed that during the three years 1948, 1949, and 1950 salaries increased by about 14%, professional earnings by over 12%, and farming incomes by 16%. . . . The apathy, disinterestedness, call it what you will, of the vast majority, so well illustrated by the acquiescence of the Annual Conference of Local Medical Committees, is, I submit, the chief reason why we now put forward our claim when a general "freeze" seems almost inevitable. The probability is that our claim will be conceded in principle and that our patriotism will be appealed to so that we may not press for our rights.

Assistants' Cars

DR. J. C. C. LANGFORD (London, W.4) writes: The position regarding cars for trainee assistants is now so serious (my own assistant's car is so ancient and so unreliable despite the fact that her name has been on the list for a considerable time) that in the not far distant future we may find that, in advertising for assistants, the doctor may consider the car before the assistant's competence, and one may in future see this sort of advertisement: "Wanted, an assistant with a reliable post-war car; send particulars of car to Box XYZ."

Association Notices

NATHANIEL BISHOP HARMAN PRIZE

The Council of the British Medical Association is prepared to consider the award of the Nathaniel Bishop Harman Prize in the year 1952. The value of the Prize is approximately £100. The purpose of the Prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best Essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has previously been published in the medical press or elsewhere will be considered eligible for the Prize. Any registered medical practitioner who is a consultant member of the staff or senior hospital medical officer of a hospital in Great Britain or Northern Ireland and who is not a member of the staff of a recognized undergraduate or postgraduate medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay, the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the Prize will not be awarded in 1952, but will be offered again the year next following this decision, and in this event the money value of the Prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

The writer of the prize-winning essay may be required to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association. Each essay must be typewritten or printed in the English language and must be distinguished by a title and a motto. The essay must not bear the name of the writer, which should be sent with the essay in a sealed envelope bearing only the motto on the outside. It is suggested that essays should consist of from 3,000 to 10,000 words. The title of the proposed essay and the motto should be notified in writing to the Secretary, and a form for this purpose can be obtained from the Secretary. Essays must reach the Secretary, British Medical Association House, Tavistock Square, London, W.C.1, not later than March 31, 1952. Inquiries relative to the prize should be addressed to the Secretary.

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for research scholarships, as follows:

An Ernest Hart Memorial Scholarship, of the value of £250.

A Walter Dixon Scholarship, of the value of £250.

Four Research Scholarships, each of the value of £200.

These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease.

Each scholarship is tenable for one year, commencing on October 1, 1952. A scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research, but may be a member of H.M. Forces or may hold a junior appointment at a university, medical school, or hospital, provided the duties of such appointment will not, in the opinion of the Science Committee, interfere with his or her work as a scholar.

Applications for scholarships must be made not later than March 31, 1952, on the prescribed form, a copy of which will be supplied on application to the Secretary, B.M.A. House, Tavistock Square, London, W.C.1. Applicants are required to furnish the names of three referees who are competent to speak as to their capacity for the research contemplated.

Diary of Central Meetings

JANUARY

- 28 Mon. Psychological Medicine Group Committee, 2 p.m.
- 29 Tues. Subcommittee on the Constitution and Procedure of Medical Service Committees, General Medical Services Committee, 2 p.m.
- 31 Thurs. Education Conference Subcommittee, International Relations Committee, 10.30 a.m.

FEBRUARY

- 1 Fri. Committee re Fees for Part-time Work under Local Authorities, 2 p.m.
- 6 Wed. General Practice Review Committee, 11 a.m.
- 6 Wed. Amending Acts Committee, 2 p.m.
- 6 Wed. Assistants and Young Practitioners Subcommittee, General Medical Services Committee, 2 p.m.
- 6 Wed. Compensation and Superannuation Committee, 2 p.m.
- 7 Thurs. Central Consultants and Specialists Committee, 12 noon.

Branch and Division Meetings to be Held

CITY DIVISION.—At Finsbury Health Centre, Pine Street, London, E.C., Tuesday, January 29, 8.30 p.m., talk by Dr. Henry Wilson: "Nervous and Naughty Children."

DARTFORD DIVISION.—At the Embassy Ballrooms, High Street, Welling, Tuesday, January 29, 8 for 8.30 p.m., annual B.M.A. dinner of the Division.

*No charge is made for the hire of these films. It is hoped that Parts V and VI, "Cervix and Uterus" and "Rectum," will shortly be available from the Film Library.

HPL RESEARCH UNIT HAS AVAILABLE for CLINICAL TRIAL

Recent experimental work suggests that H.P.C. may act as a pituitary stimulant to increase the production of endogenous A.C.T.H. and hence may be of value in those conditions which have already been shown to be amenable to treatment with this hormone. Clinical trial has partially substantiated this suggestion by showing that H.P.C. has a beneficial action in rheumatic fever, some cases of rheumatoid arthritis and in scleroderma. This compound, prepared in our research laboratories during an investigation of pituitary stimulants, is available in limited quantities for clinical trial. It is presented in sugar coated tablets of 250 m.g.

Following Radical Mastectomy a SPENCER is the Support of Choice

Therapeutically and structurally, Spencer Supports differ from other supports because each Spencer is *individually designed, cut and made* for each patient.

As an example, the Spencer Breast Support and Breast Form for the mastectomy patient illustrated were made *after* a description of all parts of the body to be covered by the Breast Support had been recorded and 14 measurements were taken.

Spencer Breast Supports are also designed as adjunct to treatment of prolapsed, engorged, caked, abscessed breasts; stasis, nodules, atrophy, hypertrophy, and mastitis.

DALMAS FIRST-AID DRESSINGS ACCELERATE HEALING

*An advanced type of
first aid dressing*

The medical profession is well aware that in spite of the advent of the sulphonamides and penicillin, 5-aminoacridine hydrochloride holds a definite place in wound therapy. Dalmas first aid dressings are now impregnated with 5-aminoacridine hydrochloride.

This effective antiseptic has a bactericidal action against *B. Proteus* and other Gram-negative organisms which are unaffected by penicillin and the sulphonamides.

This is an additional improvement to the outstanding qualities of Dalmas dressings. They are waterproof, greaseproof, and washing can be done while they are on. They stick tight, do not fray or catch in clothes; they stretch in every direction and, being skin-coloured, hardly show.

DALMAS OF LEICESTER

OTHER DALMAS PRODUCTS FOR SURGERY OR HOSPITAL

DALMAS STRAPPING A new waterproof adhesive tape in 1-yd. spools (1 inch wide). Retail price 1/- . Also in 3-yd. lengths and in 2-inch and 3-inch widths. Dalmas strapping is ideal for places where a bandage would be awkward or difficult to keep in position.

DALMAS VACCINATION SHIELDS

A new waterproof vaccination dressing of patented design. Air is able to enter through three small holes in the plastic covering, beneath which is a specially impregnated gauze to ensure that the dressing remains waterproof.

It can be partially removed for inspection. Retail price 1/-.

DALMAS SPECIAL DOCTOR'S CABINET

This enamelled metal cabinet contains 180 first aid dressings in seven sizes and shapes, with a spool of Dalmas strapping. Price 16/8, refills 14/10. It is invaluable both in the doctor's consulting room and in the home.

These products can be obtained direct from Dalmas Limited, Leicester, or through your usual supplier.

Advantages of the

Daimler Limousine Ambulance Service

It is often necessary for patients to travel by road. A normal car is usually too fatiguing, yet in many cases the patient wishes to avoid travelling in a public ambulance.

This need is met by engaging a Private Limousine Ambulance from Daimler Hire Ltd. The Ambulance has the appearance of a large private limousine and does not attract attention from the public.

A fully trained attendant accompanies each driver and both are competent stretcher bearers. Each Limousine Ambulance is specially designed for the purpose and is equipped with a swivelling bed, folding carrying chairs, canvas carrying slings and sick-room cabinet. Air beds are available if required. Two comfortable chair-seats are provided for friends. Adequate heating and ventilating is automatically assured.

★ A booklet giving full details of this service is available on request. Please write or telephone:—

APPOINTMENTS

Applicants should state name, address, age, nationality, qualifications, and enclose 3 copies (unless otherwise specified) of recent testimonials with short statement of experience and appointments held.

Applications should be sent at once if no closing date is given.

Canvassing in any form will disqualify.

★SERVICE MEMBERS may have difficulty in supplying recent testimonials, but this should not deter them from applying.

Deferment of call-up for "R" practitioners (i.e., practitioners liable for call-up under the National Service Acts) is granted at the discretion of the Central Medical War Committee and (in Scotland) the Scottish Central Medical War Committee. The Committees normally allow an "R" practitioner to hold a First House Officer post (N.H.S. salary £350 per annum) provided that he obtains it without delay. Under present arrangements the Committees also normally allow an "R" practitioner to hold a Second House Officer post (£400) and a Senior House Officer post (£670), provided in each case that the higher appointment is secured before the termination of the practitioner's current appointment.

"R" practitioners may not accept Third House Officer posts (£450 per annum) unless they have obtained the special permission of the C.M.W.C. or (in Scotland) the Scottish C.M.W.C.

SALARY SCALES OF JUNIOR GRADES OF HOSPITAL MEDICAL STAFF

Registrar Grades, Whole-time

(a) **REGISTRAR**: Posts obtained normally not less than two years after registration as a medical or dental practitioner and held normally for two years: £775 per annum in the first year; £890 per annum in the second and any subsequent years.

(b) **SENIOR REGISTRAR**: Posts obtained normally not less than four years after registration as a medical or dental practitioner and held normally for three years: £1,000 per annum in the first year; £1,100 per annum in the second year; £1,200 per annum in the third year; £1,300 per annum in any subsequent years.

Other Grades, Whole-time

(a) **HOUSE OFFICER**: £350 per annum for the first post held, £400 per annum for the second post held; £450 per annum for the third and any subsequent post held; with, in each case, a deduction at the rate of £100 per annum in respect of board and lodging and other services provided. Each post shall be tenable for six months.

The Minister will be prepared to authorize, in exceptional circumstances, salaries up to £50 per annum higher than the standard rates specified above where a post cannot be filled otherwise.

(b) **SENIOR HOUSE OFFICER**: Posts obtained normally not less than one year after registration as a medical or dental practitioner and normally held for one year only: £670 per annum.

(c) **JUNIOR HOSPITAL MEDICAL OFFICER**: Officers who have held house appointments but who are not registrars and who have less responsibility than other hospital officers of non-consultant status: £700 (for an officer appointed not less than two years after registration as a medical practitioner) by £50 to £1,000 per annum.

ALL NATIONAL HEALTH SERVICE HOSPITAL APPOINTMENTS ARE IN ACCORDANCE WITH THE TERMS AND CONDITIONS OF SERVICE OF HOSPITAL MEDICAL STAFF

Those intending to apply for resident appointments in the Registrar grades are recommended to make inquiries with regard to the deductions proposed for board and lodging at the time of submitting their applications, where this is not stated in the advertisement.

PRACTICES (Executive Councils)

For vacancies (except those in Scotland) on Form E.C.16A, obtainable from the Executive Council. Mark envelope "Vacancy."

GLASGOW

Applications are invited from registered medical practitioners (including practitioners already on the medical list of the Council) to fill the following vacancies:

(1) **Townhead district**. The number of persons on the list is approximately 590 and the practice is suitable for a woman practitioner. It is understood that the house will not be available to the successor in the practice, but that the surgery may be available for purchase.

(2) **Southern district**. The number of persons on the list is approximately 2,190. The main part of the practice is situated in the Gorbals district and the other part generally in the Cathcart area. It is understood that the house will not be available but that the main surgery in Gorbals may be available to the successor in the practice.

Forms of application may be obtained from the undersigned, with whom applications should be lodged not later than fourteen days from the date of publication of this advertisement. Applicants should state to which vacancy the application refers.—William S. Phillips, Clerk and Finance Officer, 9, Park Terrace, Glasgow, C.3.

KENTON, Middlesex

Applications invited for vacancy, urban. List at present approximately 3,700. Residence and surgery not available. Apply, on Form E.C.16A, before February 9, 1952, to the undersigned.—F. J. Ashford, Middlesex Executive Council, Gloucester House, Gloucester Gate, N.W.1.

KIDDERMINSTER, Worcestershire

Applications invited for urban vacancy, due to retirement on March 31, 1952. List at present 3,710. Residence will be for sale. Surgery (not at residence) may be available. Closing date February 9, 1952. Apply on Form E.C.16A, to undersigned.—V. T. Williams, Clerk, Worcestershire Executive Council, 29, Foregate Street, Worcester.

LEEDS

Applications are invited for vacancy in above area with a view to commencing practice on April 1, 1952. List 3,135. Residence and branch surgery available. Form of application (E.C.16A), available from the undersigned, should be completed and returned not later than February 11, 1952.—A. J. G. Miles, Clerk of the Leeds Executive Council, Trevelyan Chambers, 7, Boar Lane, Leeds, 1.

MANCHESTER

Applications are invited from doctors wishing to undertake general medical services in Manchester. Approximate number of persons on the list of the deceased doctor is 2,500, principally in Miles Platting and Newton Heath districts of Manchester. Applications, on E.C.16A (obtainable from address below), should be sent to the undersigned not later than seven days from publication of this notice.—H. Glass, Clerk of the Council, Ardwick Town Hall, Ardwick Green North, Manchester, 12.

County Health Department
DEPUTY AREA MEDICAL OFFICER

Required, initially in Area 8 (Hayes/Harington, Ruislip-Northwood, Uxbridge, Yiewsley/West Drayton) for administrative and clinical duties mainly in connexion with National Health Service and Education Acts. Must be prepared, if required, to undertake also duties of Medical Officer of Health or Deputy of one or more of the County Districts in Area, in which case salary would be amended in accordance with appropriate nationally negotiated scale. Degree or Diploma in State Medicine or Public Health and practical experience of public health administration essential. Whole-time, established. Subject to medical assessment and prescribed conditions. Salary £1,200 by £50 to £1,500 per annum inclusive. Applications, stating age, qualifications, experience, two referees, to Area Medical Officer, Local County Offices, High Street, Uxbridge, by February 23 (quoting K.364 B.M.J.). Canvassing disqualifies.—C. W. Radcliffe, Clerk of the County Council. (6897)

READING, COUNTY BOROUGH OF

Applications are invited from duly qualified registered medical practitioners for the post of **ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER**. The duties will be mainly in connection with the Maternity and Child Welfare Service and the School Health Service, but the person appointed will be expected to carry out such duties as may be allotted to him by the Medical Officer of Health. There is opportunity for experience in the Clinical Departments of the local hospitals. The salary will be on an appropriate step of the scale £850 by £50 to £1,150 per annum, according to experience and qualifications. Further particulars can be obtained from the Medical Officer of Health, Town Hall, Reading, to whom forms of application should be returned not later than three weeks after the appearance of this advertisement.—G. F. Darlow, Town Clerk. (7250)

NORTHUMBERLAND COUNTY COUNCIL

Applications are invited from registered medical practitioners for the appointment of an **ASSISTANT COUNTY MEDICAL OFFICER** to undertake duties in connexion with maternity and child welfare. Salary will be in accordance with the scale £850, rising by annual increments of £50 to £1,150 per annum, previous experience being taken into consideration in determining the commencing salary. Travelling and subsistence allowances will be paid in accordance with the Council's scale when the officer appointed is required to be away from the normal centre which, in this case, will be Blyth. The appointment is subject to superannuation, and will be determinable by three months' notice on either side. The successful candidate will be required to pass a medical examination. Forms of application may be obtained from the undersigned, and must be returned, accompanied by names of three referees, not later than January 31, 1952.—John B. Tilley, County Medical Officer, County Hall, Newcastle-upon-Tyne, 1. (6888)

ROTHERHAM, COUNTY BOROUGH OF

Health Department
Applications are invited from registered medical practitioners for the appointment of **ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER** at a salary within the scale £850 per annum by annual increments of £50 to a maximum of £1,150. The duties will chiefly concern school health and child welfare services. Forms of application and conditions of appointment may be obtained from the Medical Officer of Health, Municipal Offices, Rotherham, and must be returned to the undersigned, endorsed "Assistant Medical Officer," within 14 days of the appearance of this advertisement. Canvassing will disqualify.—John S. Wall, Town Clerk, Municipal Offices, Rotherham. (6982)

SMETHWICK, COUNTY BOROUGH OF

Applications are invited from registered medical practitioners for the post of **ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER**. The duties will consist mainly of work in connexion with maternity and child welfare and school medical inspection. The duties will also include such other public health work as the Medical Officer of Health may direct. Salary will be on the scale £850 per annum, rising by £50 annually to a maximum of £1,150 per annum. The appointment will be subject to the provisions of the Local Government Superannuation Act, 1937, and the successful candidate will be required to pass a medical examination. The appointment will be subject to two months' notice on either side. The officer appointed may, if desired, be offered the tenancy of an unfurnished flat. Forms of application may be obtained from the Medical Officer of Health, Public Health Department, Hales Lane, Smethwick, to whom they should be returned within two weeks of the publication of this advertisement.—E. L. Twycross, Town Clerk, Council House, Smethwick. (7157)

STOKE-ON-TRENT, CITY OF, EDUCATION COMMITTEE
Applications are invited from fully qualified registered medical practitioners for the post of **WHOLE-TIME ASSISTANT SCHOOL MEDICAL OFFICER**

Salary scale £850 to £1,150 per annum by annual increments of £50. The duties will consist of routine medical inspection in schools and clinic work. Experience in refraction work is desirable. The appointment is subject to the provisions of the National Health Service (Superannuation) Regulations and is terminable by one month's notice on either side. The successful candidate will be required to pass a medical examination. Forms of application, which may be obtained from the undersigned, should be completed and returned as soon as possible.—H. Dibden, Chief Education Officer, Town Hall, Hanley, Stoke-on-Trent. (6971)

INDUSTRIAL APPOINTMENTS

NATIONAL COAL BOARD, DURHAM DIVISION.—Applications are invited from registered practitioners for a full-time appointment as a **Medical Officer** in the Durham Division of the National Coal Board. The duties will embrace the normal functions of Industrial Medical Officer. The successful candidate will be allocated to an area and will be responsible for the organization and supervision of the medical and first-aid services at the collieries in that area. Candidates should have had experience in general practice and/or in the field of preventive and industrial medicine. Knowledge of the coalmining industry, though not essential, will be an advantage. Salary will be within the range of £1,250 to £1,900, according to qualifications, age, and experience. Applications, giving full particulars of age, qualifications, experience, in chronological order, present post and salary, together with the names of three referees, or three testimonials, should be sent to the Establishments Officer, National Coal Board, "D" Floor, Milburn House, Newcastle-upon-Tyne, 1, within fourteen days of the appearance of this advertisement. Original testimonials should not be sent.

Industrial Appointments—contd.

Commencing salary at rate of £1,260 to £1,660 (N.Z.) per annum, according to qualifications and experience. A new laboratory is in course of erection. The position is non-resident and housing will be appointee's own responsibility. Annual leave and sick leave are prescribed in regulations. Reasonable travelling expenses incurred by an overseas appointee will be refunded up to £150 for single man and £400 for married man accompanied by dependent relatives. The appointment is terminable by three months' notice on either side. Applicants are advised to obtain further particulars from the office of the High Commissioner for New Zealand, 415, Strand, London, W.C.2. Applications (by air mail) close with the undersigned on March 31, 1952.—W. H. J. Watson, Managing Secretary, Grey Hospital Board, Greymouth, New Zealand. (6757)

HIS MAJESTY'S COLONIAL SERVICE, Malaya

Doctors having medical qualifications registrable by the General Medical Council in the United Kingdom, with one or more years' experience after qualification, are required for appointment as

MEDICAL OFFICERS AND MEDICAL OFFICERS OF HEALTH

for general medical and health duties. A limited number of practitioners liable for call up under the National Service Act, 1948, may apply, and if appointed will be granted indefinite deferment of call up on completion of a minimum period of one tour of three years in the Malayan medical service. Appointment is available (a) on probation for permanent establishment, (b) on employment from the National Health Service, and (c) on short term contract with gratuity (a) Permanent terms. Subject to three years probation, appointment is permanent with pension (non-contributory) at age 55. Salary is paid in the scale £952 by £42 to £1,204 to £1,274 by £42 to £1,652 per annum. There are many posts, specialist and administrative, available on promotion carrying higher salaries (up to about £2,400 for the highest post). Promotion is often made before reaching the top (£1,652) of the long scale. There is also a cost-of-living allowance at varying rates, according to family circumstances, subject to maximum of £336 per annum for single men and of £707 per annum for married men with children (both rates higher when stationed in Singapore). Note. Doctors with more than one year's approved experience after age 25 (including service in His Majesty's Forces) enter the salary scale at points above the minimum according to their experience; and four increments of salary are also given to holders of approved higher qualifications (e.g. F.R.C.S., M.R.C.P., D.P.M., D.A., etc.) (b) National Health Service. Doctors may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Malayan salary on leaving Malaya at the end of their engagements. Emoluments as under (a) including incremental credit for experience and higher qualifications as in note under (a). Doctors so appointed may be considered for permanent terms at any time during their Colonial employment provided they surrender their rights to the resettlement grant and payment by Malayan Governments of superannuation contributions. (c) Contract terms. The contract will be for three years' resident service, renewable for a further tour of three years by mutual agreement. Salary and cost-of-living allowance as under (a) including incremental credit for experience and higher qualifications as in note under (a). In addition a gratuity earned at the rate of £300 to £450 per annum, according to salary, is paid on expiry of contract. Doctors on contract may be considered for appointment to the permanent establishment at any time on their agreeing to surrender their gratuity earning rights. In all three types of appointment the rates of salary and gratuity refer to doctors eligible for expatriate terms under Malayan Regulations (i.e. those whose permanent homes are in the United Kingdom, Ireland, Australia, Canada, etc.). The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Income tax is payable at Malayan rates which are lower than those in the United Kingdom. Government quarters with heavy furniture are provided at a low rental, or an allowance is paid in lieu of quarters. Free passages are provided for the doctor, his wife, and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. The social and recreational facilities in Malaya are good. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No 37215/242/51). (5187)

SOUTH GEORGIA

Wanted immediately, Doctor for a Wharfing Station at South Georgia. Higher qualifications necessary. Salary £100 per month, board and lodging provided. Applications to Medical Superintendent, Chr. Salvendy and Co., 29, Bernard Street, Leith.

OTAGO HOSPITAL BOARD

Dunedin Hospital and University of Otago

Applications are invited for the position of **HALF-TIME OPHTHALMIC SURGEON** to the Department of Ophthalmology at Dunedin Hospital

Salary, commencing at a rate between £800 to £1,000 per annum, according to qualifications and subsequently according to the Hospital Employment Salary Regulations shortly to be issued. Salary will commence on assuming duty at Dunedin Hospital. Full details may be obtained on application to the office of the High Commissioner for New Zealand, 415, The Strand, London, or to the office of this Journal. Applications, stating age, qualifications, postgraduate experience, accompanied by copies of testimonials, a certificate of health and radiological certificate and testimonials, will be received by the undersigned until 10 a.m. on February 20.—W. A. Williamson, Secretary, Otago Hospital Board, P.O. Box 453, Dunedin. (6902)

UNIVERSITY APPOINTMENTS**CRICHTON ROYAL FELLOWSHIPS**

The Board of Management of the Crichton Royal have established three Fellowships for the training of specialists in psychiatry, each carrying a salary of £670, less a deduction of £150 for the usual residential emoluments. Two of these Fellowships will fall vacant on April 1, 1952. The Fellows receive training in all branches of clinical psychiatry, including work in out-patient and child guidance clinics, by the senior members of the medical staff. The Fellowships are tenable for one year but may be prolonged for another year. Previous general hospital experience essential. Application form and syllabus are obtainable from the Physician Superintendent, Crichton Royal, Dumfries. (6779)

NUFFIELD FOUNDATION

The Nuffield Foundation invites applications from citizens of the United Kingdom for

FELLOWSHIPS AND SCHOLARSHIPS IN DENTISTRY

To help the advancement of teaching and research on dental health and disease, the Foundation is prepared to award a number of Fellowships (i) to enable selected men and women with dental qualifications to receive such additional training in pure and applied science as is desirable to fit them for an academic career in dentistry, and (ii) to enable selected university graduates in medicine and science to receive training that will qualify them to undertake teaching and fundamental research on dental health and disease. The Foundation is also prepared to award a limited number of Scholarships to assist students of outstanding ability attending a university dental school to devote one or two years to further studies of the basic sciences. Applications for fellowships should be received by March 1 annually and for scholarships by June 30 annually. Copies of the conditions of both fellowships and scholarships and the application forms are obtainable from the Secretary, The Nuffield Foundation, 12 and 13, Mecklenburgh Square, London, W.C.1.—L. Farrer-Brown, Secretary of the Nuffield Foundation. (7124)

UNIVERSITY OF BELFAST

Applications are invited for a

LECTURESHIP IN PHYSIOLOGY

at the Queen's University of Belfast. Salary £1,300 by £50 to £1,750, plus provision for superannuation. Initial placing on the scale is dependent on experience and qualifications. The lecturer will have special responsibility for dental students. A dental qualification is not necessary. Applications should be received by March 30, 1952. Particulars from G. R. Cowie, M.A., LL.B., Secretary. (7248)

UNIVERSITY OF SHEFFIELD

Applications are invited for the

J. G. GRAVES MEDICAL RESEARCH FELLOWSHIP

of £1,300 a year, tenable normally for three years. The Fellow is required to carry out full-time medical research in one of the Departments, clinical or other, of the University of Sheffield, or in a teaching hospital associated with the University. Applications (six copies), indicating the line of research proposed by the applicant, and including the names and addresses of three referees, and, if desired, copies of not more than three testimonials, should reach the Registrar, The University, Sheffield, 10 (from whom further particulars may be obtained), by February 23, 1952. Official application forms are not provided. In certain circumstances an appointment to a Junior Fellowship at a lower stipend is not excluded.—A. W. Chapman, Registrar. (7249)

**EDINBURGH POSTGRADUATE BOARD FOR
MEDICINE
GENERAL SURGERY**

A three months' course of postgraduate surgery
is arranged to start on March 24, 1952. It is
suitable for surgeons requiring a refresher course
in the current outlook on general surgery, or for
graduates preparing to specialize in surgery;
approximately 275 hours of instruction are pro-
vided. A similar course will be held starting on
September 29, 1952. Fee £31 10s.

INTERNAL MEDICINE

A course lasting twelve weeks, suitable for
graduates wishing a refresher course, or to special-
ize in medicine, begins on March 31, 1952. These
courses consist of 320 hours' instruction, comprising
lectures, clinical demonstrations and ward visits.
A similar course begins on September 29, 1952.
Fee £31 10s.

Additional instruction in Clinical Paediatrics is
arranged in conjunction with the course in Medi-
cine, for which there is a small fee; the numbers
are limited.

MEDICAL SCIENCES

A three months' course in Applied Anatomy,
Physiology, Pathology, Bacteriology and Bio-
chemistry will begin on June 30, 1952. This course
is suitable for postgraduates wishing to take the
Primary Fellowship examination, as a final prepara-
tion in these subjects. Considerable basic know-
ledge is highly desirable prior to taking this course.
Fee £31 10s.

**REFRESHER COURSE FOR GENERAL
PRACTITIONERS**

The nineteenth Fortnight General Refresher
course for N.H.I. practitioners will start on May 5,
1952. Fee for graduates not claiming expenses
from Government sources, 10 guineas.

Applications for enrolment should be addressed
to Director of Postgraduate Studies, Surgeons' Hall,
Edinburgh, 8. Applicants for courses, except
general practitioners, should supply particulars of
qualifications and postgraduate experience.

For sale, Cambridge Cardiograph, hospital type, as new, mains and battery, switch for unipolar leads. £220.—Box 328, B.M.J.

Bronze Name Plates with cream enamel letter- ing. Send size and lettering for estimate.—Osborne, 117, Gower Street, London, W.C.1.

For sale, Combined Treatment Unit, having faradic, galvanic, and sinusoidal currents. Short-wave Diathermy Machine, spark gap type, no valves. Two Radiant Heat Tunnels containing bulbs, one large, one small. Short-wave Inductotherm Machine (induction coil type). Aluminium Leg Bath.—Box 330, B.M.J.

Gramophone Records bought, sold, and ex- changed. Small lots or whole collections purchased. L.P. records supplied to order, post free, anywhere (limited stocks of second-hand copies in fine condition also available). If you cannot call send for regular lists.—H. C. Harridge, 8, Moor Street, Cambridge Circus, London, W.1.

Microscopes. Highest prices paid for good modern types. Send or bring your equipment for valuation.—Wallace Heaton, Ltd., 127, New Bond Street, W. (May 7511).

Name Plates in bronze, brass and plastic, etc. Estimates and sketches free.—A. T. Brown & Co., Ltd., 347 and 349, Katherine Road, London, E.7. Tel.: GRA 1024.

HOMES

NORTHUMBERLAND HOUSE GREEN LANES, FINSBURY PARK, N.4

A PRIVATE HOSPITAL for the treatment of MENTAL and NERVOUS ILLNESSES. Conveniently situated and easy of access from all parts. Six acres of ground, facing Finsbury Park. Voluntary and Temporary Patients received without certification. E.C.T. Group psychotherapy. Trained Resident and Visiting Staff: INSULIN COMA UNIT. Telephone: Stamford Hill 7866/7 (2 lines). Telegrams: "Subsidiary, London." Medical Superintendent, Robert M. Riggall, Member, British Psycho-Analytical Society.

CAMBERWELL HOUSE

33, PECKHAM ROAD, LONDON, S.E.5
—Telephone: Rodney 4242 (2 lines)

A PRIVATE HOSPITAL for the Treatment of Nervous and Mental Disorders. Full particulars may be obtained from the Secretary. The Convalescent Home is HOVE VILLA, BRIGHTON.

OXFORD UNIVERSITY PRESS

An Announcement...

HEPARIN-BOOTS reduced in price

BOOTS PURE DRUG CO. LTD. are pleased to announce that, due to increased yield and greater productivity, HEPARIN-BOOTS and its preparations are now available at substantially reduced prices.

INJECTION OF HEPARIN B.P.-BOOTS

5 ml. rubber-capped vials of 1,000; 5,000;
or 25,000 I.U. of HEPARIN B.P. per ml.

HEPARIN RETARD

2 ml. ampoules, each containing 20,000 I.U.
of HEPARIN B.P. in a modified Pitkin's
menstruum. Boxes of 6.

HEPARIN POWDER

Vials of 20,000 and 100,000 I.U.

Literature and further
information from the
Medical Department,
Boots Pure Drug Co. Ltd.,
Station Street,
Nottingham.

In established nasal infections

'PENDEX' *provides*

prompt and

prolonged

vasoconstriction

plus

**the potent
bacteriostasis
of penicillin**

Penicillin (unlike the sulphonamides) is not inhibited by the presence of pus, and has proved highly effective both in acute sinusitis and in flare-ups of chronic sinusitis.

'Pendex'—providing the bacteriostatic action of penicillin, plus the aeration and drainage effected by* 'Paredrinex'—has proved particularly useful in such conditions.

'Pendex' can be used to irrigate the sinuses, followed by the displacement technique; or it may be administered by tampon.

* 'Pendex' contains 1% 'Paredrinex' (p-Hydroxy Amphetamine Hydrobromide, S.K.F.)

PENDEX

— the penicillin-vasoconstrictor for intranasal use

Available in 15 ml. ($\frac{1}{2}$ -oz.) bottles, on prescription only

MENLEY & JAMES, LIMITED, COLDHARBOUR LANE, LONDON, S.E.5

for Smith Kline & French International Co., owner of the trade marks 'Pendex' and 'Paredrinex'

HEPARIN PRICES

REDUCED AGAIN!

SINCE THE WAR, despite the rising costs of raw materials and labour, the price of PULARIN (HEPARIN-EVANS) has been reduced by 64% as illustrated.

THE LATEST PRICE reduction is operative from 1st February, 1952 and is due to increased production and manufacturing economies.

PULARIN
TRADE MARK
(HEPARIN-EVANS)

Rubber capped vials of 5ml. containing 1,000, 5,000 and 25,000 i.u. per ml.

Containers of 100,000 i.u. dry powder.

Heparinised tubes containing 100 i.u. of Pularin.

Boxes of 3 tubes.

PULARIN IS MADE IN ENGLAND BY

TABLETS: 10 micrograms in packs of 50 and 500

AMPOULES of 1 c.c. each containing 20 micrograms, 50 micrograms
or 100 micrograms—in boxes of 6

IN CASES OF PERNICIOUS ANÆMIA

*the pure vitamin B₁₂ has quickly been accepted as the most effective, and much the
most comfortable and convenient, form of treatment.*

VITAMIN B₁₂ DEFICIENCY IN CHILDREN

*American authors have reported the successful treatment with Vit. B₁₂ of what may
be termed B₁₂ functional deficiency in children who were making slow progress, were
suffering from varying degrees of malnutrition, or were in various stages of recovery
from simple growth failure.*

*Medical literature and clinical samples may be obtained on
application to Dept. A.59*

VITAMINS LIMITED, UPPER MALL, LONDON, W.6

Treatment of the Streptococcal Throat

'PONDETS' Penicillin are a new and ingenious vehicle for local oral penicillin therapy that combine the striking advantages of extreme palatability with prolonged action. Each 'Pondet' contains 5,000 international units of crystalline potassium penicillin-G in a delicious hard, fruit, toffee-like base that completely masks the bitter taste of penicillin.

Because of the nature of their hard base, 'Pondets' dissolve slowly and uniformly, supplying an uninterrupted high concentration of penicillin to infected areas of the oro-pharyngeal mucosa.

INDICATED in minor superficial oral infections due to penicillin sensitive organisms ranging from the 'Streptococcal Throat' to the less common Vincent's infection and recommended for routine prophylactic use following Tonsillectomy.

Individually wrapped in bottles of 20.

Children accept 'Pondets' as readily as a sweet, and they are particularly useful in controlling throat infections in juvenile communities.

'Pondets' Trade Mark **PENICILLIN TROCHES**

TREATMENT OF EMBOLISM AND THROMBOSIS OF THE CEREBRAL VESSELS*

BY

RENÉ LERICHE, M.D., F.R.C.S.(Hon.)

Professeur au Collège de France

I should like to call your attention to the possibility of influencing cerebral circulation by very simple methods in cases of cerebral vascular accident caused either by embolism or by thrombosis. I shall not concern myself here with head injuries justifying surgical intervention at the site of the haemorrhage, but will refer only to medical cases in which coma can be alleviated in a few minutes and the extent of the hemiplegia considerably reduced.

I should like, too, to tell you about the hypothesis that has guided me in my clinical researches on this matter for 25 years. I started from the same general pathological principle which I tried to verify in other parts of the body: autonomic dysfunction—that is, a vasomotor disturbance—usually precedes, often causes, and practically always accompanies such a vascular accident.

In the case of the cerebral circulation, I presupposed that isolated spasm could exist, comparable to that which may be observed in the limbs. And particularly I thought that such a spasm would always accompany the occurrence of an embolism or thrombosis, causing around the ischaemic area perifocal zones of diminished circulation.

I knew that the then prevailing ideas did not take into consideration the possibility of vasomotor reactions in the cerebral arteries. It was claimed, with a certain degree of finality, that the brain circulation was protected from vasomotor fluctuations by some extracranial regulating system. About 1920 I undertook to investigate this question. In various clinical conditions, working mostly on war-wounded who had undergone brain surgery, I performed what I called an "internal carotid sympathectomy"; in other words, I removed as much as I could of the tunica adventitia of the internal carotid, starting from its bifurcation. Immediately the artery would contract; then the retinal vessels diminished in calibre and the retinal pressure dropped. After a few hours a vasodilatory reaction would be observed, evidenced by dilatation of the same retinal vessels with rising of the retinal pressures. Simultaneously the flattened trephine scars would be seen to swell. When dealing with patients with Jacksonian epilepsy due to war

injuries, I would first perform this internal carotid sympathectomy under local anaesthesia, then immediately after, still under local anaesthesia, widely open the skull to excise the arachnoid cortical scar tissue. The cortical vessels of those patients were so constricted that it appeared to me that this operation should provide a means of ensuring preliminary haemostasis in brain surgery, and at the time I reported a number of operations performed in this fashion. Denervation of the carotid body gave the same results.

This substantiated the idea that the small brain arteries had their own vasomotor control. Moreover, it was histologically confirmed that the pia mater and intracerebral arterioles had a double innervation of myelinated and amyelinated fibres. This was not consistent with a total functional inactivity. At any rate, from that time on it seemed to me that it was possible to modify the activity of the cerebral blood vessels by surgical intervention, and I should like to give you two examples of what can be accomplished.

Effects of Resection of a Thrombosed Common Carotid Artery and of Pericarotid Sympathectomy in Certain Intracranial Conditions

Case 1

A 35-year-old man was sent to me in 1941 on account of a painful paralysis of the brachial plexus. Because of considerable dysarthria he had great difficulty in telling me how he was wounded by a bullet which entered through the left side of his neck and came out below the scapular region. His arm was paralysed immediately. Picked up by the Germans, he discovered that he could no longer talk. He had complete aphasia, no hemiplegia, but very unpleasant tingling sensations in the right leg. He was repatriated on account of his wound, and when I saw him I noted the following three points:

1. Complete paralysis of the deltoid, supraspinatus, infraspinatus, biceps, triceps, pronator, and supinator muscles. The movements of the hand were normal. I supposed that there must have been an injury of the upper branches of the brachial plexus. The patient complained of acute pains in the arm.

2. A considerable degree of dysarthria; his voice was smothered, non-bitonal, and there was a slight hemiplegia on the right side.

*Being a lecture delivered at the Institute of Neurology, London, on July 3, 1951.

3. In the neck region a long scar extended over the site of the carotid junction, suggesting a carotid lesion. The most careful palpation could detect no carotid beat. It was my impression that the aphasia must have been caused by sudden ischaemia of the brain. I therefore examined the other side and found a slight but unmistakable hemiplegia with hyperaesthesia of the abdominal wall and a definite Babinski sign.

The hospital neurologist concurred in the diagnosis of definite signs of a pyramidal lesion. Examination by the laryngologist showed a paralysis of the hemilarynx with hemianaesthesia, but the difficulty of speech was ascribed to a central lesion. I therefore decided to perform a double exploratory operation: one to verify the condition of the left carotid, and another to explore the left brachial plexus.

Nineteen months after the initial injury I found the common carotid in a mass of scar tissue. In its lower part, and up to the bifurcation, the artery was like a cord filled throughout with scar tissue. Lower down, the artery had the shape of a spindle ending at the site of the obliteration, which began about 2 in. (5 cm.) from the clavicle, and a blood stream seemed to circulate from the external to the internal carotid. The vagus nerve was oedematous, and in the middle of it was a cicatricial neuroma. I injected procaine hydrochloride and resected the whole of the obliterated carotid segment. Histological examination showed an organized thrombosis.

In the evening some improvement of speech could be observed as well as a retrocession of the pain in the neck and shoulder. From this time the patient's condition continued to improve; speech became easier, and the signs of hemiplegia decreased. I shall make no mention of the laryngeal condition, of the second operation on the brachial plexus, or of the arthrodesis of the shoulder which was rendered necessary by paralysis of the deltoid.

When the patient was seen several years later his speech was almost normal and he had regained an important part of his movements. He could carry out his agricultural activities almost normally, and was married.

This case shows clearly the influence of resection of the thrombosed carotid on an old focus of cerebral ischaemia. Nothing is changed in the circulatory mechanism after the arteriectomy, and yet a great proportion of the symptoms attributable to a central lesion have decreased in a short time. This can be explained only by modifications of the vasomotor conditions comparable to those observed after performing an arteriectomy on a limb. It was my impression that the carotid had not been cut by the bullet, but had only been bruised. The endothelium had probably been torn, as I have observed on several occasions in arteries of the limbs. A spasm had certainly occurred at once, since the aphasia was immediately present. Then thrombosis set in. The circulation was re-established by a reversal of the blood stream into the external carotid, so that the ischaemia was of short duration. A zone of ischaemic necrosis resulted—at the margin of which perifocal circulatory disturbances manifested themselves—and disappeared after the arteriectomy.

Case 2

A priest was wounded on May 25, 1940. While crawling to the front lines he suddenly felt a shock, tried to stand up, and fell unconscious. He remained several days without being able to talk or move, and his hospital notes contain the following observations: "Right hemiplegia with aphasia, amnesia, visual disturbances, and meningeal reaction." When he became conscious again he could only utter some inarticulate sounds. During the next few weeks there was some improvement, and after two months he began to read and was able to make some movements. But he could not keep his attention on anything, and most of the time he could not understand what he was reading or what he was being told.

I saw him six months later, in January, 1941. About 2 in. (5 cm.) from the sternum, inside the carotid line, I found the entrance scar of the bullet, which had gone out at the back, near C6. Carotid pulsation was present. There was evidence of a regressing right hemiplegia. The patient walked with a circular swing. He could only move his hand slowly and with difficulty. The reflexes were exaggerated, and a facial weakness was present. There was also a left Claude Bernard syndrome and a lesion of the lower branches of the brachial plexus with atrophy of the thenar and hypothenar muscles. There was anaesthesia of the C8-T1 territory: He had stuttering dysarthria. Ideation was slow, with lapses. The patient could not make conversation and could not follow a lecture. He forgot things, and was unable to say mass through lack of memory.

In view of the presence of carotid pulsation I felt that the ischaemia must be due to a spasm. I decided to try an infiltration of the left stellate ganglion. The result was extraordinary; in a few minutes speech improved, and ideation became easier. The rhythm of the conversation was entirely changed, and this improvement persisted until the next day.

During the next few days 11 injections were made in the stellate ganglion, all with favourable results, so that the patient was soon able to say mass again. In view of this, on January 17 I decided to operate. Under local anaesthesia the carotid was exposed; this artery was not obliterated, and pulsations were present above and below the scar area. At this point, however, it was immobilized by sclerosis of the tunica adventitia, which was removed entirely up to the bifurcation. The same evening the patient could speak much more easily and stated that he could think almost normally. After a few more days I noted that the improvement of both speech and ideation was maintained. Moreover, there was a definite improvement of hand movements, especially of the index and middle fingers, which could be moved independently; this had been impossible. Walking was unchanged. After 10 days the patient went home delighted with the results obtained.

Eight years later he wrote me: "I take part in discussions and in all conversations. My speech is still improving. Reading remains 50% slower than it was. My right leg is almost normal. I can ride a bicycle 30 to 40 kilometres without fatigue. My memory is quite fair, though not completely restored."

This case is very instructive. The results of the first injection in the stellate ganglion were really dramatic. In less than one minute speech was transformed, and so was ideation. All this can be accounted for only by vasomotor modification of the brain arteries, and indicates that functional disturbances were added to the original ischaemic lesion. The pericarotid sympathectomy had the same permanent results. I cannot find any other explanation than that of an arrested activity of some of the brain vasoconstrictors.

It appears, therefore, that perverted circulation in the neighbourhood of a zone of ischaemic necrosis of the brain can be modified by working on some organ outside the brain.

Local Vasomotor Autonomy of the Cerebral Arteries

To the above I wish to add some clinical observations which seem to indicate that there exists a sort of autonomy of the vasomotor vessels of the brain, although this is not a recognized fact in physiology. Pathological physiology will sometimes reveal possibilities of reactions which experimentation cannot demonstrate. At a time when the methods of haemostasis had not yet been perfected, it was possible to observe in the course of some surgical procedure, or when clipping a vessel, a sudden local vasodilatation evidenced by congestion and an immediate oedema which would hide everything from view. Similarly, in cases of trauma of the brain, small haemorrhagic zones may be observed at a distance from the site of the traumatic lesion, and

sometimes even in the brain stem or in the bulb, which can only be due to diapedetic haemorrhage of vasomotor origin.

This shows that vasomotor reactions in the brain are not always of extracerebral origin and that they may be the consequence of a local injury.

Localized or Clinical Spasms

Observation on patients suffering from disturbance of the cerebral circulation, especially those who probably have had a stroke, reveals some facts which can be interpreted only as resulting from a local spasm of the brain arteries.

First, one will occasionally find in patients suffering from high blood pressure a disappearance of the transient manifestations following a cerebral vascular accident, which cannot be accounted for by anything but excessive vasoconstriction. All of a sudden aphasia will be present, sometimes with paraesthesia of an arm or leg; then everything disappears without leaving any trace, and this for a long period. At times such manifestations will precede a stroke by several months, or even several years. In one case in which the symptoms had lasted several hours a stellate-ganglion block cleared the aphasia in a few seconds.

There are cases, too, in which coma occurs only after hours of slight paralysis. Recently I saw a 42-year-old physician who woke up one morning with a left facial paresis. He attended to his business the whole morning, had lunch as usual, carried out his customary activities in the afternoon, and went out in his car; but towards the end of the day he experienced some difficulty in driving. After he got home, paralysis progressively invaded his arm, then his leg, and finally he became comatose. The coma lasted until the next morning. He recovered from it, but the hemiplegia persisted.

These facts led me to think that in cases of accidents to the brain vessels there always is added to the thrombosis, or to the embolism, a vasomotor reaction which enlarges the field of ischaemic disturbances producing coma.

Attempts at Section of the Cervical Ramifications in Hemiplegia

On the basis of this hypothesis, in 1925 I performed a section of the communicating cervical ramifications on a patient suffering from hemiplegia. There was considerable improvement. Royle had already performed an identical operation, but his object had been to relieve the contraction, whereas my own objective was to modify the circulation. I have always expounded the principle that surgery of the sympathetic system is above all concerned with vasoconstriction.

Subsequently I made three other such operations with appreciable results. In 1936, in a case of Wallenberg (Babinski-Nageotte) syndrome with hemiparesis and hemianaesthesia, the presence of grave angina pectoris attacks induced me to perform a stellectomy. The heart attacks disappeared and there was at the same time considerable improvement of the hemiparesis, ataxia, and lateropulsion. The improvement still persisted after a year.

Attempts at Treatment of "Strokes" by Stellate-ganglion Block

In 1932 I had obtained remarkable results by performing a stellate-ganglion block in a case of hemiplegia due to birth traumatism in a young boy. This fact, added to previous observations, gave Fontaine and myself the idea of trying to treat strokes due to embolism by infiltration of the stellate ganglion. We had an occasion to do this on May 5, 1936.

On that date I was called at 8 a.m. to see an obese woman who, a week before, had undergone hysterectomy for a voluminous fibroma and who had suddenly become comatose. She did not respond to any form of stimulation. Her

breathing was very irregular. Death appeared imminent. An injection was immediately made in the stellate ganglion (approximately an hour after the onset of the symptoms) on the left side, as the right limb seemed more inert than the left one. After five minutes breathing became more even and the pulse slower. Half an hour later the coma subsided and the patient responded to stimulation by groaning. In the afternoon her condition was completely changed: her breathing was no longer stertorous, and the pulse was regular. Hemiplegia still persisted, but the aphasia seemed to be regressing. The next day another injection was given, as a result of which the patient was able to speak slowly but very distinctly, without stuttering. She was also able to move her fingers very slightly. Two more injections were made in the stellate ganglion during the following days, and after each one the motility was improved. After a week speech was clear. The limbs were gradually regaining their movements, although these were still slow and spastic, and there was a persistent Babinski sign. In spite of this the hemiplegia was obviously regressing.

At the beginning of June the patient got out of bed; she dragged her leg in walking. The movements of her right arm were clumsy and slow, and she could not raise her arms above the level of the shoulders. Improvement continued during the next few weeks, and the movements of the fingers became easier.

On August 3 she was sent home with only faint traces of her hemiplegia and a perfectly normal cerebral function.

Undoubtedly the stellate-ganglion block saved this patient and promoted favourable progress. We made the mistake, both Fontaine and I, of not continuing the infiltrations, and perhaps, too, of not having given her two a day. This would probably have shortened her convalescence.

A few months later we were presented with a new case of cerebral embolism in a 56-year-old woman following removal of a uterine polyp. On the third day after the operation there appeared a slight facial paralysis with aphasia and right hemiplegia. Respiration and pulse were normal. An injection was immediately made in the stellate ganglion; half an hour later the patient could, with difficulty, pronounce a few words—she could slightly move her fingers. In the afternoon the improvement became more pronounced: speech, though still difficult, was intelligible. The movements were slow and feeble, but nevertheless present. The next day another infiltration was made, bringing about further improvement. The movements were easier and speech was improving. The next day, except for a slight difficulty in talking and some weakness of the movements on the right side, no trace of the accident to the brain was left. It would have been impossible to know that three days previously the patient had complete hemiplegia. Her reflexes had become normal again—and the recovery lasted.

These two observations were published in the *Revue de Chirurgie* in December, 1936. They did not make much impression in spite of the fact that we had suggested applying this method in cerebral vascular accidents and pointed out that it could occasionally be of great help in cases of hemiplegia of old standing, could improve speech in cases of aphasia, and could reduce the spasticity.

In 1938 Mackey and Lawrence Scott reported in the *British Medical Journal* (vol. 2, p. 1) a group of 19 cases of apoplexy treated by stellate-ganglion block. Nine of the patients showed improvement. Most of the failures were in cases of severe cerebral haemorrhage in old people; it should be noted, however, that Claude Bernard's syndrome was not always present, as it should be if the anaesthetic really reaches the stellate ganglion.

In 1948 Geza de Takats and Gibert tried this method on 25 patients who had had a stroke a few hours before. In 19 cases the results were favourable.

In August, 1950, Naffziger and Adams published in the *Archives of Surgery* (vol. 61, p. 286) a report covering 225 cases, for which a total of 700 stellate-ganglion blocks were

made; 155 of these patients had acute cerebral vascular accidents—thrombosis, embolism, or vasospasm—and 70 suffered from acute neurological deficiency due to trauma or brain surgery. The results were classified as good when recovery was complete, fair when there was only partial recovery, and poor when there was no immediate or subsequent improvement.

In the first group, comprising 155 cases, the result was good in 91 (59%), fair in 37 (24%), and poor in 27 (17%). In the second group, comprising 70 cases, the result was good in 30 (43%), fair in 30 (43%), and poor in 10 (14%). The authors' conclusion is that the stellate-ganglion block should have a definite part in the treatment of cerebral vascular disturbances.

My own experience is less extensive than Naffziger's. The following, however, is the procedure I should advise in such cases:

Make the infiltration as soon as possible on the opposite side to that of the paralysis. Begin with 10 ml. of 1% procaine. Make another injection of 20 ml. six hours later; then continue with one infiltration a day for fifteen days. There seems to be some advantage in occasionally giving the injection on the side of the paralysis and even in associating a lumbar infiltration with the stellate-ganglion block.

I might add that some physicians have observed a modification of the electrocardiographic curve following stellate-ganglion block; moreover, as I reported long ago, it also modifies the spinal fluid pressure.

Recently, A. de Souza Pereira, in view of the favourable results obtained by stellate-ganglion block 50 hours after the occurrence of an embolism, resected the middle-ganglion and the intermediate and upper part of the stellate ganglion, thereby obtaining a marked improvement in the patient's condition. Encouraged by this result, de Souza Pereira treated a number of hemiplegias of more or less long standing by sympathetic block followed by sympathectomy. He sometimes obtained progressive improvement—dramatic in some cases, slight in others—some patients regaining useful movements, while others were scarcely benefited. In order to clarify these facts further, de Souza Pereira experimented on dogs.

After tying the two internal carotid branches, he performed an arteriography, then a sympathectomy, and finally followed this by another arteriography. It was easy to observe on the arteriogram how the circulatory track was enlarged by the operation.

He then used the same method of arteriography to study the effects of ganglionectomy on man. The interruption in the sympathetic chain caused an increase in the blood circulation. Lubsen had already, in 1941, come to the same conclusion, but it was his impression that unilateral ganglionectomy, while increasing the blood flow on the operated side, diminishes it on the opposite side. It therefore appears from this that the intervention should be bilateral.

At the present stage of research, however, I do not believe that a sympathectomy should be performed too soon—I mean immediately after the stroke—on the human being. The stellate-ganglion block seems sufficient to give the desired results.

For the time being I would perform a sympathectomy only on patients who, after one or several cerebral episodes, live in terror of the future—perhaps with good reason. I have operated on this indication eight times during the past fifteen years. Because of the war I lost track of six of my patients. Here is one case report, however, which will make it possible to judge the efficacy of the method.

A man aged 49 had had mild diabetes for a long time. On November 6, 1948, while talking, he suddenly stuttered and could not finish his sentence. After a few seconds his malaise disappeared and he was able to talk again, but he had the impression that his left side was all cold, numb, and senseless. His movements were awkward, slow, and difficult. His blood pressure was 230/90 mm. Hg. From

that time onwards the patient could walk only with difficulty, dragging his leg; the movements of his arm and leg were slow and incomplete, and the whole left side felt numb. He was forced to reduce his business activities considerably. He had difficulty in expressing himself and often had fits of dizziness.

He came to see me at the beginning of June, 1949. I noticed some difficulty of speech and the remnants of a left hemiplegia. Both arm and leg had lost considerable strength; there was hypoaesthesia of the left side, but not total anaesthesia. A feeling of constriction above the left knee annoyed him very much.

His blood urea was 28 mg. per 100 ml.; blood sugar 108 mg. per 100 ml., blood pressure 170/90 mm. Hg. An arteriography showed normal arteries.

On June 30, under local analgesia, I performed a section of the roots of the vertebral nerve on both sides. As usual the operation was followed by intense cephalalgia, which disappeared after a few days.

Twenty months later the patient came to see me for an arteritis of the leg. He stated that a few weeks after the operation he was able to resume his professional and family life, having regained his faculty of speech. He now spoke at a normal speed, without hesitation, and finished all his sentences. It would have been impossible to guess that he had a past history of disturbances of speech. Both arm and leg had regained normal strength; all movements were easy, though there persisted a feeling of numbness and the feeling of constriction above the knee was still present. Everything else was normal. His blood pressure was 170/90 mm. Hg.

Another patient, operated on in similar clinical circumstances a few months ago, is very much satisfied with the results obtained so far.

In all these cases I did not do a ganglionectomy but merely a section of the vertebral nerve roots at the upper pole of the stellate ganglion, as this suppresses most of the constrictors of the basilar artery.* The future will tell what the true value of this operation is. It must be remembered, however, that this operation, which should always be performed bilaterally, in either one or two stages, is followed for a few days by intense cephalalgia, probably due to meningeal congestion. This operation should perhaps be resorted to as a complement to the classical surgical treatment of patients having high blood pressure with cerebral manifestations, and also, perhaps, of those who have severe visual disturbances.

Stellate-ganglion Block in Old Hemiplegias

In cases of long-standing hemiplegia we must for the present be content with the results obtained from repeated stellate-ganglion blocks.

Since 1935 I have tried the stellate-ganglion block in a great variety of cases of hemiplegia. I began with those in which the patients complained of pain, and have generally succeeded in suppressing or at least attenuating the pain. Then I extended this form of treatment to patients whose condition was comparatively recent. Since 1945 I have treated over 100 patients by repeated infiltrations (from 12 to 36). It is impossible for me to give statistics and percentages, owing to the fact that the cases treated varied considerably in severity, extension, and duration. The general impression, however, is that the more recent the case the greater the chance of success; yet it is possible to obtain favourable results after several years. At all stages of the disease a number of failures must be expected: the result can be either insignificant or negative.

In some patients changes will indicate a functional share in the establishment of symptoms. For example, a 45-year-old woman stricken with aphasia was able to say a few

*A report on this operation was published in *Arch. ital. Chir.* 1938, 52, 659.

words within the hour following the stellate-ganglion block ; then she gradually sank back into mutism.

Approximately one-third of the patients have a feeling of relief, are less contracted, and are more supple ; and many walk very much better after a week. This improvement may be temporary, and sometimes the former condition will re-establish itself when the infiltrations are stopped. Or the improvement may be permanent, especially if the patient is determined to collaborate.

An example of this is the case of a 42-year-old physician who had had hemiplegia for 18 months, with a blood pressure of 200/100 mm. Hg, and had walked with difficulty, using a stick ; the arm movements were incoordinate. After 39 stellate-ganglion blocks on the opposite side to that of the paralysis he can walk without his stick, and is now planning to resume some of his activities.

In another case, a man who could not hold a pencil in his contracted hand could, after 16 infiltrations, carry for fifteen minutes a basket filled with fruit.

Possibly these patients who can still be improved by delayed stellate-ganglion blocks could be benefited by sympathectomy. In my opinion they represent 25% of the cases I have treated, but I must say that for reasons of humanity I have made an attempt in some very old cases—of four to five years' duration. Let us hope that in the future such patients will be treated at an earlier stage. We must think of the despair of these unfortunate people abandoned without hope to their terrible fate.

Pierre Stricker, a neurosurgeon from Mulhouse, after performing a stellate-ganglion block for a two-year hemiplegia and seeing the patient resume his occupation, has since 1942 treated several cases of hemiplegia by repeated infiltrations of the upper cervical ganglion, and has just recently published some case reports which fully confirm those recorded above.

A recent attempt has been made to treat hemiplegia by carotico-jugular anastomosis. This operation does not seem to increase the number of arteries visible on the angiogram : the blood is mostly diverted into the veins, which become dilated, especially in the bulbar region.

According to the results of our experiments, the simplest and most efficient method seems to consist in giving emergency stellate-ganglion block treatment in cases of embolism and thrombosis, and, for patients who have missed this early chance, to resort to treatment which may vary from infiltration to resection of the thrombosed carotid and the various methods of sympathectomy—section of the vertebral nerve roots or ganglionectomies.

Conclusion

These are the facts and comments I wish to submit. I do not think that I have unduly emphasized the extent of the results obtained.

If it is true, as I have read, that there are each year in the United States 500,000 cases of apoplectic strokes and hemiplegia, I feel that a method which makes it possible to diminish the importance of these accidents deserves some consideration. There is, moreover, another side to the question—the tragedy brought into the life of those who survive the stroke by the persistence of hemiplegia and particularly aphasia. A famous American magazine some months ago very clearly described the facts which I have just stated, and gave the principles and results of the stellate-ganglion block. Since then I have received 200 letters, from different countries of the world, expressing the despair of those whom we call, without conscious irony, "cured apoplectics."

Anyone reading such distressing messages cannot fail to wish for the development of a method which would considerably minimize the gravity of the accident.

FURTHER OBSERVATIONS UPON THE DIAGNOSIS OF DEAFNESS IN YOUNG CHILDREN

WITH PARTICULAR REFERENCE TO THE MAKING
OF RECOMMENDATIONS FOR SPECIAL
EDUCATIONAL TREATMENT

Since our first description of the peep-show technique for pure-tone audiometry in children under the age of 6 years (Dix and Hallpike, 1947), the equipment has been in regular use at weekly clinics at the National Hospital, Queen Square. In the course of this work certain developments have taken place.

In the first place, the mechanism of the equipment has been greatly improved and reconstructed in a simple and readily reproducible form. Secondly, we have had the opportunity during the examination of the considerable number of subjects involved—350 in all—of becoming familiar with certain technical and psychological difficulties which may arise in the course of the testing procedure, and have been able to formulate effective means of recognizing and overcoming these difficulties.

Furthermore, in the course of these investigations we have been asked to make recommendations, upon the basis of our findings, for the special educational treatment (S.E.T.) of the children in accordance with the well-known classification of deaf children proposed by the Board of Education (1938) in its special report. Here certain interesting difficulties have been encountered. Finally, we have been able in a number of cases to carry out a follow-up with a view to assessing the validity of our educational recommendations.

The publication of the present communication has, therefore, the following aims : (1) to give a detailed account of the mechanical improvements in the apparatus ; (2) to describe the psychological and other difficulties which may arise in the course of the test procedure and the methods of overcoming them ; (3) to describe and discuss our clinical material and test results ; (4) to describe and discuss the problems arising in connexion with the making of recommendations for S.E.T. ; and (5) to give the results of our follow-up.

Apparatus—1. The Child's Equipment

The general lines of the tests and of the peep-show equipment are best illustrated by two diagrams reproduced from our original paper (Figs. 1 and 2). The test procedure depends upon the conditioned response of the subject to a series of short pure-tone stimuli delivered from a loud-speaker. These pure-tone stimuli are synchronized with the

FIG. 1.—Diagram of the peep-show test apparatus.

flashes of a signal lamp. The child sits in front of the wooden box shown in Fig. 1, within which are displayed a series of attractive pictures. In order to be seen, these pictures have first to be illuminated by the child by the pressing of a button. Thereafter he inspects them through a viewing aperture. This press-button mechanism works only when the synchronized light/sound stimuli are being delivered. The stimulation mechanism is under the control of the tester, who observes the child closely from behind a screen. The pure-tone stimuli are variable in frequency in fixed octave intervals from 256 to 4,096 c.p.s. The intensity is calibrated in decibels above the threshold of hearing of a normal subject with his head in the position of the test subject. During the test an instructor is seated on the subject's right hand, and performs the important functions of controlling the child, encouraging him to co-operate in the test, and of changing the picture by the operation of a simple mechanism when necessary.

The test begins with the instructor focusing the child's attention on the viewing orifice. When the tester observes that this has been accomplished he applies the double signal, and the instructor at once presses the button, illuminates the picture, and encourages the child to inspect it.

When this has been done the tester withdraws the signal and the picture disappears. After this demonstration has been repeated two or three times the child soon learns to press the button and illuminate the picture when, and only when, the double signal is being given. As soon as this reflex has been established the next step is to eliminate the light signal in the front of the box. This the instructor does by closing a simple shutter over the light. The test is then continued, using the interrupted sound stimuli only. In subjects without hearing this elimination of the light signal makes further response impossible; on the other hand, in subjects with sufficient hearing to detect the sound signal the elimination of the synchronized light signal makes no difference to their response and they continue to react to the sound signal alone. The intensity of the sound signal is then reduced progressively until a threshold reading is obtained. In Fig. 3 is shown a photograph of the equipment in its present form, as seen by the subject.

In order to gain his fullest co-operation it is important that the child should regard the peep-show as some attractive toy or game, and the design of the apparatus has thus been kept as simple and as small as possible. The box is painted in a gay colour with decorations carefully calculated to make the viewing-hatch the centre of attraction. This should be on the child's eye level as he sits comfortably in front of the box. The signal lamp is placed close enough above the viewing hatch to be included within the child's field of vision when he is inspecting this hatch. It should also be rather dull and inconspicuous in comparison with the brilliantly illuminated picture. Furthermore, the mechanism of its elimination—that is, by closure of a simple shutter—should be obvious to the child.

The child's press-button mechanism should be of the simple bell-push variety; it needs to be of comfortable size, easy to work, and conveniently situated for operation by his right hand. Anything in the nature of a hand-rest in the vicinity of the bell-push is better avoided, as this usually results in the child keeping his hand very near or on the switch, and his responses are thus made more difficult to observe. Two

FIG. 2.—The apparatus in use.

FIG. 3.—Photograph of equipment in its present form as seen by the subject.

small pilot lights are provided in the side of the box which faces the tester. These indicate to him the proper functioning of the signal lamp and the illumination of the pictures. The viewing aperture is closed by glass, which serves the purpose of preventing the child interfering with the picture. In addition, the reflections from the glass make it difficult for the child to see anything of the unilluminated picture. Details of the internal mechanism of the apparatus are given in Fig. 4.

2. The Pictures

It is important that the pictures should be brightly coloured and of suitable size. The size used is $7\frac{1}{2}$ by $6\frac{1}{2}$ in. (19 by 16.5 cm.). We find the pictures most easily obtainable from suitable magazines and books. They are mounted on thin aluminium plates made up into magazines of 25 to 30, which are loaded into the back of the apparatus at the beginning of a test. It is important to select pictures suitable for the age and sex of the subject, and this can easily be arranged. They are changed from time to time in the course of the test; this is done by the instructor by a simple string mechanism which operates very rapidly and quietly. It is seldom that more than 25 pictures are required for a full audiometric test.

3. The Tester's Equipment

That part of the equipment used by the tester—that is, the tone generator, interrupter switches and their associated circuits—has not been substantially modified from that described in our original paper. The output of a beat-frequency oscillator is led by way of a 60-decibel attenuator (input attenuator) to a power amplifier and thence through a 40-decibel attenuator (output attenuator) to a 12-in. (30.5-cm.) moving-coil loudspeaker. This arrangement of attenuators has been found necessary for the maintenance of background noise at a level insufficient to constitute a stimulus. This is, of course, a matter of great practical importance. For example, the deafness in certain subjects may be confined to the higher frequencies, with normal or near-

normal hearing within the chief frequency range of 50 cycles mains' hum. Unless measures are taken with such subjects to keep the hum level below signal level at normal threshold intensity throughout the range of test frequencies, spurious responses will be obtained at the high frequencies to the hum alone and an apparently normal audiogram will result.

By far the greatest part of the background noise arises from the amplifier, and its elimination could thus be effected by introducing all the attenuation needed between the amplifier and the loudspeaker. This, however, would be impracticable, as the power dissipated would call for resistance elements of gross physical dimensions.

Our own arrangement of the attenuation has proved quite adequate in fulfilling the need for a background noise level which is well below the signal level at normal threshold intensity throughout the test frequency range. With this arrangement, threshold determinations up to 60 decibels above the normal threshold are made by variation of the input attenuator alone, with the output attenuator set at its full attenuation of 40 decibels. For the higher intensity levels the output attenuation is reduced.

Interrupter Switches.—These are operated by hand. We have tried automatically operated switches, whereby it is possible to apply sound stimuli at a uniform rate, free from onset transients. In practice, however, we have seldom found that such transients, which arise from a simple rotatory switch in the output of the amplifier, have any significant disadvantage. Moreover, the use of such a switch simplifies the apparatus, and accordingly facilitates variations by the tester of the interruption rate and duration of the stimuli. Such variations are very important for the avoidance of monotony in the test procedure.

Test Procedure and its Difficulties—1. Management of the Children

Experience has demonstrated the vital importance of the correct management of the children both before and during the test. Careful attention must be paid to the following details.

Preparation

It is essential that the children should not be presented for the test when tired, hungry, or otherwise unfit. They are therefore always seen by appointment after a carefully worded letter of instructions has first been sent to the parents; without such precautions children may be presented in a rather peevish and fretful state, which makes accurate testing impossible.

FIG. 4.—Internal mechanism of the apparatus.

Preliminary Interview

This is of great importance. It is a mistake in the course of this interview to attempt any examination of the ears, nose, and throat. Also, the avoidance of white coats by the examiners is of definite assistance in many cases. One examiner plays with the child with a few simple toys on a table, while the second examiner takes the history from the parents. No other spectators should be present at this stage of the interview. In its course, both examiners are able, by observing the child's performance and reactions, to gain some useful impressions both of the state of his intelligence and of his hearing. An electrically operated Klaxon horn is placed behind the child, concealed from him by a screen. This can be operated by one or other of the examiners in the course of the interview and, if heard by the child, nearly always evokes a well-marked reaction which can easily be observed. In the case of a very shy or nervous child rapid co-operation can often be obtained by first allowing him to observe another child playing with the toys.

This interview should not occupy more than 5 to 10 minutes, and it is necessary in its course for the examiners to be convinced, first, that the intelligence of the child is sufficient for the peep-show procedure, and, secondly, that his friendly co-operation has been obtained. The part played in this interview by the examiner in charge of the child, in thus gaining his confidence and introducing him to the test, is certainly a vital one. It is not, however, a very difficult role, and should certainly be within the powers of any intelligent person with a liking for children, given reasonable experience. In the course of this interview it is possible also to pick out certain classes of children who are obviously unsuited for the test, and to recognize certain others who may require special management.

Types of defect which render children unsuitable for the test include:

Mental Defects.—A normal mental age of 3 years is required for the peep-show procedure. The toys and games used in the interview are matched to this level of mental attainment. Any striking inability to manipulate the toys nearly always indicates a mental age of less than 3 years. In such children we always proceed with the peep-show test, but seldom find this possible to carry out.

Visual Defects.—The peep-show procedure is impossible without a visual acuity sufficient for the appreciation of the pictures. This point is carefully checked during the interview.

Motor Defects.—Children with paralysis or severe ataxia may be unable to co-operate in manipulating the press-button switch.

Before proceeding to the test the child's mother is carefully warned of the need to remain quite quiet during the course of the test, and that she should content herself, if referred to by the child, with the adoption of an encouraging demeanour. On no account should she give the child any instruction, in particular "not to touch."

2. Management of the Test

General Considerations.—The intensity regulation of the initial sound stimulus is a matter of some importance. Thus a child with a considerable degree of residual hearing may be disturbed by an initial sound signal of 100 decibels. It is generally possible in the course of the preliminary interview to obtain some indication whether the hearing loss is very slight or very severe, and the initial intensity is regulated accordingly. In general this is set at 80 decibels.

Manipulation of the Pictures.—Once the test is under way and the child has been brought to the point at which he illuminates the picture himself, it is important to allow him sufficient time to inspect it before withdrawing the signal and so eliminating the illumination. The changing of the pictures should be done by the instructor as unobtrusively as possible in order not to deflect the child's interest from the viewing-hatch to the picture-changing

mechanism. The frequency with which a picture needs to be changed depends very much on the character of the child. With an attentive or enthusiastic subject the same picture may maintain his interest for some time.

The duration of the test procedure seldom exceeds 12 to 15 minutes. This applies to rather difficult cases and to cases with relatively little hearing loss in which a large number of responses are required. In co-operative children with severe hearing losses the test procedure may be shorter than five minutes.

3. Difficulties

These fall into two main groups: first, difficulties which occur at the start of the test; and, secondly, difficulties which occur in the course of the test.

Difficulties Arising at the Start of the Test

These occur with certain types of children and may make it impossible to get the test procedure under way at all. The types of children concerned may be described under the following headings:

Timid and Apathetic Children.—Most of these appear to be children with an unhappy or unnatural home background. Some had been brought up by foster parents, others in institutions; others, again, appeared to have suffered from the effects of parental severity: all conditions which seemed to have had the effect of destroying natural curiosity and enterprise. The timid children would do nothing without first gaining the approval of the instructor or parent, and great patience and perseverance were needed to elicit in such a child the necessary spontaneous responses. It has often proved most helpful to allow a child of this kind to watch another operating the peep-show. In the apathetic children spontaneous responses occur, but only with sound intensities well above threshold. This is a serious cause of incorrect threshold readings, with exaggeration of the apparent deafness. A failure of interest on the part of the child and a lack of uniformity in his responses generally indicate this difficulty, which may also be accentuated by the use of unsuitable pictures. We have on a few occasions found it necessary to make repeated observations on children of this kind before arriving at a reliable estimate of their deafness, sometimes without the presence of the parents.

The Restless Child.—Certain restless and enterprising children persist, at any rate at the beginning of the test procedure, in pressing the bell-push at random without any signal being given. This situation requires careful management on the part of the tester, who must give the signal at a moment when the child is in an expectant attitude but not apparently preparing to make such a random movement. This is of great importance. Thus, in the case of a deaf child, unable to hear the sound signal, if this is given at a moment which coincides with a random movement the child will be rewarded by seeing the picture. He will not, however, appreciate that this is a reward for a correct response to an audible signal; and, being thus encouraged to indulge in further random movements, will speedily be confused and discouraged from further co-operation. Certain interested children may persist in keeping their finger on or near the button between signals. This, of course, makes observation of the responses very difficult, and must be corrected by removing the child's hand. This must be done gently and with great tact, since in certain cases it appears to discourage the child from further co-operation.

Difficulties During Course of Test

Once the child's spontaneous response to the dual signal has been obtained, the light-shutter is closed and the sound signal is applied alone. Here we reach the crucial part of the test procedure. In favourable cases, and these are the majority, no difficulty arises. The child responds without hesitation to the sound signal and thus leaves the examiners in no doubt that it has been heard. In certain children, however, in whom the preliminary interview has established the likelihood of a fair amount of residual hearing, the

child may give no definite response to the sound signal alone. The difficult situation which then arises may be analysed as follows:

(i) The child hears the sound signal, but for some reason does not understand the need to respond to it in the absence of the light signal. A little experience with the test almost always makes this situation clear. Thus, at the moment of the sound signal the child will nearly always move his hand in an arrested response, or he may look inquiringly at the instructor. Such a movement accurately synchronized with the signal will generally be apparent to the tester on careful scrutiny. If this is detected the child can then be encouraged openly to press the bell-push, when the test generally proceeds without further difficulty.

(ii) Certain children may hear the sound signal but refuse to press the button until they have first satisfied themselves of the coexistence of the synchronized light signal. Such a child will respond at once to the sound signal by first opening the light shutter. On seeing the light he will proceed at once to press the button and illuminate the picture. This sequence of responses does not, of course, invalidate the test, and need not at once be checked.

(iii) Certain children respond very slowly. Indeed, the response to the sound signal may be delayed for as long as 8 to 10 seconds. The cause for this is obscure; nevertheless, this delayed response may occur quite constantly without change of the delay interval, and may be relied upon.

(iv) Certain totally or very severely deaf children may have given a false impression to the examiners at the preliminary interview of having a considerable degree of hearing. Most of these children are highly intelligent, have remarkably good speech, and may be good lip-readers. The faulty assessment of their hearing at the preliminary interview thus occasioned may result in the peep-show procedure being begun with the sound signal of insufficient intensity. Failure to respond on elimination of the light signal may then indicate a degree of deafness which is quite correct but, nevertheless, surprising to the examiners. This situation is met by reverting to the double signal with much higher sound intensities.

4. Procedure After the Test

After completion of the test procedure a detailed examination of the ears, nose, and throat is carried out. The report of our findings, which is finally sent to the appropriate educational authority, comprises information upon the following points: (1) the cause and pathology of the deafness; (2) the prognosis; (3) the possibility of relieving the deafness by means of treatment; (4) the degree and audiometric character of the deafness; and (5) the possibility of alleviating the deafness by means of hearing-aids. Finally, recommendations are made for S.E.T. as fully discussed below.

Our examination findings, taken in conjunction with previous otological reports, have made it clear in most cases that the deafness is due to some neurolabyrinthitis or other irreversible pathological process occurring during gestation or in early post-natal life. In such cases clear advice is given that no treatment is likely to effect improvement and that further deterioration of hearing must eventually be expected. In other children otolaryngological examination may make evident the possibility that the deafness is due, at any rate in part, to some catarrhal otitis likely to be improved by treatment. It is, of course, of the greatest importance to recognize such a cause for the deafness and to advise appropriate surgical treatment—for example, removal of tonsils and adenoids, and insufflation of the Eustachian tubes. When this course is advised it is wise to postpone a final estimate of the deafness and any recommendations relating to S.E.T. until the treatment has been completed and a further audiometric test made. We have observed a number of children of this kind with very severe deafness due in part to an inner ear affection, but with

obvious catarrhal changes in the tympana associated with enlarged tonsils and adenoids. Removal of the tonsils and adenoids has in these cases greatly reduced the degree of the deafness and substantially modified the character of S.E.T. recommended.

Clinical Material and Test Results

We have investigated with the peep-show a total of 350 children with a view to determining the possible part played by deafness in the production of backwardness in speech and in other ways. The age distribution of these children was as follows:

Age	No.	Age	No.
2 years	10	5 years	61
3 "	80	6 "	44
4 "	68	Over 6 years	87

Of this total, the tests were successful in 302 and unsuccessful in 48. The latter group is discussed first.

Unsuccessful Tests.—The causes of failure are shown in Table I. It will be seen that failure to carry out the tests was attributable in 45 cases to some obvious mental, visual,

TABLE I

Age Group (Years):	2	3	4	5	6	Over 6	Total
Mentally defective	1	9	13	3	1	8	35

Total	3	17	13	5	2	8	48

or motor defect. The three unexplained cases of failure all occurred in our earlier experiences with the peep-show, before the present equipment came into use.

Successful Tests.—In 42 of the 302 cases successfully tested by the peep-show technique it was impossible for a variety of reasons to proceed to recommendations for S.E.T. for backwardness due to deafness alone. Some of the children were in need of preliminary treatment for disorders of the ears, nose, or throat likely to be concerned with their deafness, while others required special management for other defects. These 42 cases are classified in Table II.

Problems Arising in Connexion with the Making of Recommendations for S.E.T.

In the remaining 260 cases in which the test was successful the question arose of making recommendations for S.E.T. Our chief aim in endeavouring to bring about an improvement in the technique of pure-tone audiometry in these children has, of course, been to establish the pure-tone audiogram as a more efficient basis for such recommendations, and in this we have followed the pioneer work of the Ewings, of Manchester, whose well-known publications constitute a notable landmark in the history of this difficult subject (Ewing, 1930). Due emphasis is also laid upon this point in the report of the committee of the Board of Education, in which it is pointed out that deafness assessment is the most important single factor in determining the character of the S.E.T.

A further passage worthy of quotation appears on page 42 of the committee's report: "The analysis of the acuity of hearing by examination with the pure-tone audiometer forms a scientific basis for the provision of a hearing-aid or the teaching of speech to a child with defective hearing . . . records of the hearing of their children should be available to teachers of Grade II and Grade III children." Our primary aim has been to make such records available to educational authorities after solving the technical difficulties of obtaining them. We have, in addition, extended the scope of our reports in most cases to the making of specific recommendations for S.E.T. on the basis of the committee's well-known classification of deaf children. Here, of course, considerable difficulties have arisen, as the problems involved in the making of such recommendations extend clearly beyond the domain of auditory capacity alone and must ideally include, as duly emphasized in the committee's report, an expert assessment of speech development, vocabulary, mental capacity, lip-reading ability, and a number of other faculties which it is proper to describe as lying beyond our scope.

No great difficulties have been encountered in assessing the mental capacity, and we can certainly say that the behaviour of our subjects, under the conditions of our preliminary interview and during the test itself, has seldom left us in any doubt about the presence or absence of any significant degree of such mental defect. Furthermore, following their recognition by ourselves, such defects have always been confirmed in a subsequent expert examination by a child psychologist. This applies to all of the 49 children specified as mentally defective in the preceding Tables.

In the assessment of speech defects, vocabulary, and lip-reading ability our difficulties have, of course, been much greater. In nearly all of our subjects the speech defects were obvious ones, due, as shown by the clinical history and subsequent audiometry, to a failure of speech development resulting from deafness occurring within the first two to three years of life. We have attempted no precise analysis of its characteristics.

For the purposes of recommendations for S.E.T. our material might be summarized as consisting with few exceptions of children of normal or near normal mental capacity suffering from failure of speech development due to deafness in infancy of which the audiometric characteristics have been reliably determined. We have divided them upon an audiometric basis into groups which correspond fairly closely to those of the well-known classification

of deaf children recommended in the report of the committee of the Board of Education (1938).

Our audiometric classification is as follows:

Average Decibel Loss for 1,024 and 2,048 c.p.s.	
Group I	Less than 30 decibels
" II	30-40 "
" III	40-80 "
" IV	80-100 "
" V	Greater than 100 decibels

Groups I, II, IV, and V are discussed first.

Group I.—This corresponds on the whole to Grade I of the Board of Education, with a slightly lower hearing-loss limit—30 instead of 35 decibels. All 17 of these were backward children, and 11 exhibited speech defects attributed to causes other than deafness.

Group II.—This corresponds approximately to the higher audiometric strata of Grade IIA of the Board of Education.

Groups IV and V.—These correspond to the Board of Education's Grade III. In both we emphasize that hearing-aids should be tried. We indicate that these are likely to help in Group IV, but unlikely to help in Group V.

Group III.—This group is an important one—in the first place on account of its size, the total number of subjects being 133. It is important, too, on account of the difficulties of which we have been conscious in accurately assigning all the subjects concerned to one or other of the Board of Education's educational grades. In most cases the amount of the audiometric loss, taken in conjunction with the mental capacity and our very rough estimate of speech development, has made appropriate a provisional assignment to Grade IIB. Our recommendation in these cases has been for education as a partially deaf child in a school where hearing-aids are available. In certain children of our audiometric Group III we have been aware of the possibility that backwardness in speech development, vocabulary, lip-reading, etc., might well necessitate education in a school for the deaf—that is, that their educational grading should be III and not IIB. Such a differentiation, however, has not lain within the scope of our own examination, and we have in these circumstances thought it appropriate to make a provisional recommendation in accordance with the higher grading, IIB.

Results.—The audiometric classification of our material is given in detail in Table III, in which our audiometric grades are set off against the grades of the Board of Education to which they approximately correspond.

TABLE III

Grading and Educational Management of Deaf Children as Recommended by Board of Education* (1938)		Authors' Audiometric Grading	Age Groups (Years) of Subjects						
			2	3	4	5	6	>6	Total
Grade I (decibel loss <35).—Children with defective hearing who can nevertheless without special arrangements of <i>any kind</i> obtain proper benefit from the education provided in an ordinary school—elementary, secondary, or technical		Group I (decibel loss <30)	0	1	4	4	4	4	17

* The Board of Education was superseded in 1945 by the Ministry of Education. The "ordinary" schools referred to in the report and in the present paper are now known as primary or secondary schools.

Follow-up

With a view to ascertaining the practical value of the peep-show test procedure in prescribing the educational management of these deaf children, we have recently followed up a number of our cases. We selected 40 children whose ages fell into the following groups:

Age	No.	Age	No.
3 years	14	6 years	5
4 " "	11	Over 6 years	2
5 " "	8	Total	40

In 35 of these cases it was possible to carry out the test successfully; in five this was impossible. In one the failure of the test was attributed at the time to defective vision due to a congenital cataract which made it impossible for the child to see the picture. In the other four cases the failure was attributed at the time to mental defectiveness, and this diagnosis was confirmed when we came to follow them up. In 33 of the 35 successful cases recommendations for S.E.T. were made as follows:

Group II	..	..	..	..	1 case
" III	..	..	..	..	14 cases
" IV	..	..	..	..	4 "
" V	..	..	..	..	14 "

In each of the groups specified above, the intelligence of the children was normal or near normal. The remaining two children were successfully tested but were not recommended for S.E.T. on account of suspected mental defect, later confirmed. In the course of the follow-up, reports were obtained in all 40 cases from the teachers and others in charge of the children's education. The information obtained from this follow-up is set out below under the headings of the four groups, with illustrative case histories. Groups II, IV, and V are considered first.

Group II

The single child in this group had been educated, in accordance with our recommendation, in an ordinary school.

Fig. 5.—Audiogram of P.R.

time. Follow-up: Recommendation accepted by school M.O. Teacher's report (two years later): "Quite up to standard; no hearing-aid used."

Group IV

In all four children in this group our recommendations for education in a special school for the deaf had been accepted, and in three admission had been secured at the time of the follow-up, with satisfactory reports of progress. In particular, hearing-aids were found to be useful.

J.H., a boy aged 4, began to speak at 16 months but made very little progress after admission to a sanatorium at that age for tuberculous glands. Now responds only to loud voices. Examination: Appeared to have no speech. Played intelligently; responded to hooter. Ears, nose, and throat healthy. His audiogram is shown in Fig. 6.

Fig. 6.—Audiogram of J.H.

Recommendation: Special school for severely deaf. Hearing-aid likely to help. Follow-up: School M.O. recommended admission to special unit for deaf children attached to ordinary school. "Medresco" hearing-aid supplied. Teacher's report (one year later): "Makes good use of his remaining hearing. Benefits from hearing-aid; intelligent, and progressing well."

The audiograms of the other three children in Group IV are shown in Fig. 7.

Fig. 7.—Audiograms of other three children in Group IV.

Group V

All 14 children in this group had been educated in accordance with our recommendations in special schools for the deaf. Satisfactory progress was reported by the school authorities in all. In only two was a hearing-aid reported to be of any value.

J.M., a girl aged 4, talked at 14 months. Speech has not progressed since meningitis at 3 years 8 months. Repeats nursery rhymes, etc., but intonation faulty. Examination: Would not speak. Played intelligently; no response to hooter. Ears, nose, and throat healthy. Fig. 8 shows her audiogram. Recommendation: Special school for deaf. Hearing-aid unlikely to help. Follow-up: School M.O. recommended admission to day school for partially and totally deaf children where group hearing-aids used. Teacher's report (one year later): "Has settled down very nicely. Remembers a certain amount of language she had before her illness. 'S,' 'N,' and 'T' sounds are missing. Lip-reading very good. Hears nothing with amplifier."

Fig. 8.—Audiogram of J.M.

In addition to J.M., seven other subjects in Group V had some residual hearing. Their audiograms are given in Fig. 9.

Fig. 9.—Audiograms of seven other children in Group V.

Group III

All of the 14 children in this group had been recommended by ourselves for education as partially deaf children, in accordance with a Board of Education grading of IIB.

In three cases the school M.O.s had preferred an educational grading of IIA and in two others a grading of III. In all five of these subjects the appropriate educational

arrangements had been in force for some time at the period of our follow-up. In the other nine subjects our educational grading of IIB was accepted by the school M.O.s. At the time of the follow-up, however, five were still awaiting admission to schools for the partially deaf, and four of these were meanwhile continuing attendance at ordinary schools. Case histories of three subjects in Group III are appended.

M. R., a boy aged 3, had meningitis at 13 months. Says "mummy" and "daddy," but little else. Mother thinks he is slightly deaf. *Examination:* Would not speak. Played intelligently. Brisk response to hooter. Nose and throat healthy. Tympanic membranes dull and retracted. His audiogram is shown in Fig. 10.

FIG. 10.—Audiogram of M. R.

FIG. 11.—Audiogram of L. L.

FIG. 12.—Audiogram of S. R.

FIG. 13.—Audiograms of 14 children in Group III, lying within the shaded area.

16 months later: "Progress in past nine months largely due to quickness in imitating child sitting next to her. Good at manual work and knitting. Can hear story only if very close to teacher." Mother reported that the hearing-aid was very useful at school.

S. R., a girl aged 3. Maternal rubella second to third month of pregnancy. Babbles constantly. Says "mum" and "no"; no other words. Mother does not think she is deaf. *Examination:* No speech. Very shy, but played intelligently. Responded to hooter. Ears, nose, and throat healthy. Fig. 12 shows her audiogram. *Recommendation:* Special school for partially deaf. Hearing-aid to be used. *Follow-up:* School M.O. recommended school for deaf. Medresco aid supplied. Teacher's report (two years later): "Too severely deaf to be taught language except as deaf child. Benefits from aid. Very strong voice. Lip-reading better than speech. Progress satisfactory."

The audiograms of the 14 children in Group III lie within the shaded area in Fig. 13. In 9 of these cases Medresco aids had been supplied and were reported as useful. In two cases no aid had yet been tried. Of the remaining three cases, in which an aid had been tried without benefit, two of the subjects were mentally backward in addition to their deafness and could not manage the aid for this reason, while the third had recently been supplied with spectacles and found both devices too much to manage.

Discussion

The results of our investigation call for particular consideration under the following headings: (1) the accuracy of the audiometric test results; (2) the practical relationship between these test results and the ability of the subjects to understand connected speech; and (3) the validity and practical value of educational recommendations made upon the basis of our examination findings, of which the most important is the pure-tone audiogram.

Accuracy of the Audiometric Test Results

The most convincing evidence of the accuracy of the test results is that which we have derived as examiners from our personal observations of the several hundred children whom we have had the opportunity of observing during the course of the tests, in particular the alacrity of their responses and the repeatability of the threshold values. It has also been possible in a few children to carry out pure-tone audiograms by means of conventional audiometer tests in addition to the peep-show test. In these cases we have found that the peep-show readings give results which correspond very closely to the readings obtained for the better ear with the conventional audiometer. Fig. 14 shows the pure-tone audiogram and peep-show test results in a particularly co-operative child aged 5.

FIG. 14.—Pure-tone audiogram and peep-show test in a co-operative child aged 5.

Some comment is perhaps called for upon the fact that with the peep-show audiogram we have contented ourselves with a measurement of binaural hearing capacity. This we have done, as it is the unaided hearing capacity which determines the child's disability and therefore the character of the S.E.T. required. Furthermore, the conditions of our examination make impossible the extra expenditure of time which would be needed for the separate testing of the two ears. It is, of course, helpful to have this additional information, particularly when hearing-aids are to be used, and a modification of the peep-show procedure which makes this possible has recently been described by Denmark (1950). Telephone receivers were employed, and the procedure was used for deaf subjects in the Liverpool School for the Partially Deaf, where more time is available for the examination than is possible under the conditions of our own tests.

It is necessary also to add that, given particularly favourable circumstances—that is, opportunity for prolonged or repeated examinations with particularly co-operative or intelligent children—it is often possible in children under the age of 6 years to obtain very serviceable pure-tone audiograms by means of the conventional pure-tone audiometric procedure, using telephone-receivers. Such conditions, however, rarely occur in our own clinic.

Relationship Between the Pure-tone Audiogram and Hearing Capacity for the Conversational Voice

The problem involved here is a well-known one and needs to be considered in relation to the pathology of the deafening disease. Dix, Hallpike, and Hood (1949) discuss the matter in some detail and give results of pure-tone and speech audiometric tests carried out in a large number of adult subjects suffering from a variety of deafening diseases. The conclusions reached may be stated as follows: that in the case of simple conductive deafness—that is to say, due to disease of the conducting mechanism of the ear, in particular the middle ear—pure-tone audiometric losses are related to the hearing loss for connected speech in the comparatively simple manner which was fully described in our previous paper (Dix and Hallpike, 1947).

When, however, the deafness is of the so-called perceptive type, arising from disease of the inner ear or cochlear nervous pathways, the relationship of the pure-tone audiometric loss to the hearing capacity for speech is more obscure; in general the latter is likely to be greater than that predictable from the pure-tone audiogram.

The term "perceptive deafness," however, is a comprehensive one and includes a variety of pathological processes affecting quite different nervous elements of the cochlear mechanism, and in other papers (Dix, Hallpike, and Hood, 1948; Dix and Hallpike, 1950) it has been shown that failure of speech comprehension is a particular characteristic of perceptive deafness due to disease processes affecting the hair cells of Corti's organ. On the other hand, in perceptive deafness due to lesions affecting the fibres of the eighth nerve or the physical constitution of the fluids of the inner ear speech comprehension may be relatively good and is much assisted by hearing-aids as in the case of conductive deafness due to middle-ear lesions. It is quite clear, therefore, that the practical relationship between the pure-tone audiogram and hearing capacity for speech cannot be discussed intelligently without reference to the pathological processes concerned.

In the case of young children much less can be said of the pathological processes responsible for deafness, as in very few of them is it possible to carry out reliable bone-conduction tests, still less up-to-date investigations such as loudness recruitment tests, upon which we have come to rely as a diagnostic index of active hair-cell disease. There is, however, a good deal of collateral evidence that in many of our own subjects the deafness has been due to some affection of the inner ear and eighth nerve—that is, a neuro-labyrinthitis occurring during gestation or early post-natal life. While hair-cell damage is known to be one of the features of the pathological processes involved, other features, such as cochlear-nerve degeneration and physical changes in the labyrinthine fluids, are also known to occur, and it seems to us that these latter factors are likely, at any rate in part, to be the cause of the residual deafness which was present at the time of our examination. Certainly it must be said that tinnitus, which is a particular feature of active hair-cell disease, is not as a rule complained of by deaf children. For these reasons, therefore, it seems unwise to assume for the present that the perceptive deafness of children is necessarily of the so-called uncompensated type in which hearing for the conversational voice is relatively bad, unrelated to the pure-tone audiogram, and difficult to correct by means of hearing-aids.

It is hoped to make the pathological processes involved in the deafness of children the subject of a further communication.

Validity and Practical Value of the Educational Recommendations

The evidence obtained from our follow-up, although not comprehensive in view of the small number of subjects involved, nevertheless provides good support for the validity of our educational recommendations in respect particularly

of Groups IV and V. Some difficulty has arisen in the case of the 14 subjects comprising our Group III, in only nine of whom had it been found advisable to accept our recommendation for an educational grading of IIB. In the case of the remaining five subjects an educational grading of III had been preferred, mainly on account of severe speech defects, and it seems necessary to say that in this group pure-tone audiometric findings need to be reinforced for the purpose of educational recommendations by a more elaborate evaluation of speech development than anything we have attempted. It may be supposed that such an examination might ideally be carried out by a competent authority—for example, a teacher of the deaf—as an immediate complement to our own examination of the hearing, and of the ears, nose, and throat. Here, however, certain difficulties arise, and much must obviously depend upon the practical circumstances of the case. It would appear, for instance, that in many subjects a final assessment of suitability, particularly in respect of speech development, etc., can best be made by the headmasters of the special schools for which the children are recommended.

If this be the case, and if these headmasters require such interviews as a matter of routine for the purpose of making assessments, then it would seem that provisional recommendations for S.E.T. made upon the basis which we adopted have much to be said for them, provided always that the error rate involved is as low as that shown by our follow-up.

In other respects the aims of our examination procedure would seem to be satisfactory, as also the claim that can be made for its results—namely, that it is possible, by its means as perhaps by no other, to put at the disposal of the educational authorities concerned information upon the causes and character of the deafness, in particular the pure-tone audiogram, which must continue to provide in their hands an essential basis for the educational treatment of deaf children.

Summary

In a previous communication (Dix and Hallpike, 1947) a description was given of the peep-show equipment and its use in the diagnosis of deafness in young children. The advantages of the equipment are summarized again as follows: (1) Pure-tone audiograms greatly facilitate the making of recommendations for S.E.T. in deaf children. They are obtainable by means of the peep-show procedure in nearly all subjects of normal intelligence within the age group 3 to 6 years. (2) The test is carried out rapidly and nearly always in the course of a single interview. The length of the examination, including a preliminary interview for case-taking, seldom exceeds half an hour. (3) The technique is simple and does not require long or difficult training on the part of the examiners. (4) Stress is laid upon the well-known practical advantage of the pure-tone audiogram in facilitating subsequent observations upon the progress of the deafness. (5) The examination provides a useful measure of the subject's mental capacity.

These claims have been substantiated by tests carried out in the course of the past four years on some 350 cases. In the course of this work certain improvements have been made in the mechanism of the equipment, and a full description of these improvements is given.

Certain technical and psychological difficulties which may arise during the testing procedure are discussed. Particulars are given of the means we have found most effective for overcoming these difficulties.

The results obtained in 350 cases are described. In 260 of these, educational recommendations were made upon the basis of the pure-tone audiometric findings. For this purpose we have employed a classification based

upon the audiometric findings which is closely related to the educational grading of deaf children prescribed by the Ministry of Education.

The validity of the audiometric findings and of the educational recommendations based thereon was investigated in the course of a follow-up of 40 children, the results of which are described and discussed.

Consideration is also given to the relationship between the pure-tone audiogram and the hearing capacity for the spoken voice. Emphasis is laid upon the fact that this relationship depends essentially upon the pathology of the deafening disease.

It seems justifiable to assume that in the majority of deaf children pure-tone audiometry provides a useful measure of hearing capacity for speech.

It is a pleasure to acknowledge the great help that we have received in the course of this work from a number of our colleagues. Dr. J. L. Dunlop, county medical officer, Hertfordshire, and Mr. Henry Sharp, aural surgeon, Hospital for Sick Children, Great Ormond Street, have referred many patients to us for examination. Mr. R. Bolam, of the staff of the Otological Research Unit, devised and constructed the mechanism of the present peep-show, which has now stood the test of several years' hard work. Mr. Bernard Adams kindly designed and executed the decorations. Miss A. E. Young, aural almoner, Hospital for Sick Children, and many teachers of the deaf and other school authorities have all rendered great assistance. Finally, Dr. J. L. Burn, medical officer of health, Salford, Mr. Terence Cawthorne, and Dr. J. E. A. Underwood of the Ministry of Education, have all read the manuscript and made valuable suggestions.

The peep-show equipment has been constructed by Marconi Instruments, Ltd., upon the basis of our specifications and was recently put on the market by them.

Rabies incidence has been declining steadily in Israel since the start of the intensive nation-wide campaign in October, 1950, according to Dr. Martin M. Kaplan, chief veterinary officer of the World Health Organization, who recently returned from a visit to that country. The Israel anti-rabies campaign, which is being waged with the assistance of W.H.O., includes, among other measures, a mass vaccination of dogs with a new vaccine which has proved harmless to them and seems to give a greater immunity of longer duration than other vaccines so far produced. The number of rabies cases in animals has dropped from an average of 100 a year before the start of the campaign to 10 (one bull, one jackal, and eight unvaccinated dogs) in the course of the past 15 months. All dogs in Israel have been registered, and vaccinated animals have received suitable identification. All stray dogs are being destroyed, while newborn animals are vaccinated when they reach 6 months of age. Vaccination is compulsory and free of charge. Although it is still too early to determine to what extent vaccination alone has brought about the fall in rabies incidence in animals, Dr. Kaplan believes that the concentrated attack has played an important part in this matter. The drop is mirrored also in the decline in human deaths from rabies, which were none in 1951, whereas they numbered 20 between 1948 and 1950. In addition the number of people receiving Pasteur treatments following dog bites, which averaged 4,000 a year before the start of the campaign, has been cut to about one-half.

HABITUAL ABORTION

FURTHER OBSERVATIONS ON THE PROPHYLACTIC
VALUE OF PROGESTERONE PELLET
IMPLANTATION

BY

P. M. F. BISHOP, D.M., M.R.C.P.

Endocrinologist to Guy's Hospital and Chelsea Hospital for Women, and to the Department of Obstetrics and Gynaecology, Postgraduate Medical School of London

AND

N. A. RICHARDS, M.D., M.R.C.O.G.

Chief Assistant, Chelsea Hospital for Women

Recently we (Bishop and Richards, 1950) reported on a series of 45 patients with a history of habitual abortion who had received an implant of progesterone during the pregnancy under consideration. The results, which are shown in Table I, were commented upon by Dr. Richard Doll as follows: "Provided the 'normal'

TABLE I.—Results of First Series (45 Cases)

No. of Successive Abortions Immediately Preceding the Treated Pregnancy	No. of Patients	Outcome of Treated Pregnancy		Percentage Successful Results
		Success	Failure	
A. Primary Habitual Abortion				
2	20	18	2	90
3	8	7	1	88
4 or more	5	3	2	60
B. Secondary Habitual Abortion				
2	8	6	2	75
3	1	1	0	} 100
4 or more	3	3	0	
C. Primary and Secondary Habitual Abortion Combined				
2	28	24	4	86
3	9	8	1	89
4 or more	8	6	2	75

incidence of spontaneous abortion is of the order of 10% and the incidence of abortion due to recurrent factors is not much less than 0.1%, it is reasonable to conclude that the present figures indicate an effect of treatment. Should, however, the true incidence of 'recurring' abortion be of the order of 0.01%, the present results could easily be attributed to chance."

The Biological and Medical Committee of the Royal Commission on Population (1949) concluded that "the proportion of all pregnancies ending in spontaneous abortion may be placed between the relatively narrow limits of 7 and 11%." Javert (1948), analysing 56,803 pregnancies, found the incidence of primary habitual abortion—that is, three or more consecutive spontaneous abortions beginning with the first pregnancy—to be 0.3% and the incidence of secondary habitual abortion to be 0.2%. Malpas (1938), studying about 6,000 pregnancies, found the incidence to be 1.4%, and Bishop (1937), analysing 2,687 case histories from the Guy's Hospital Maternity Service, found that 0.4% of women had more than one initial idiopathic abortion at less than five months, and that 0.1% had three initial idiopathic abortions. Since the publication of our paper, Ripman (1951) has analysed 2,474 case histories from the Guy's Hospital Maternity Service and has excluded the last recorded pregnancies in order to diminish the error due to incomplete information concerning these last pregnancies. He has found an overall abortion rate

of 10.5%, but there were not enough cases in the series to provide evidence of the incidence of, or the prognosis in, "habitual abortion."

The results of our first series of 45 cases were open to the criticism that there were only 13 cases of primary habitual abortion and four cases of secondary habitual abortion, with three or more previous abortions, which had been treated with pellet implantation, and, although in 14 (82%) of these treatment had been successful, this represented a rather small series upon which to base any firm conclusions. For this reason we have now analysed a further series of 40 cases.

Material

This series represents *all* the cases coming under our definition of "habitual abortion" treated by us with progesterone pellet implantation at Chelsea Hospital for Women since June, 1950, with the exception of five cases, discussed in detail below. Direct information concerning the outcome of the treated pregnancy was obtained in each of these cases.

We have defined "habitual abortion" as "idiopathic" abortion before the end of the fifth month of pregnancy occurring on two or more consecutive occasions immediately preceding the pregnancy in which pellet implantation has been used. Abortion is regarded as "idiopathic" if no recognized organic cause has been found. "Primary" habitual abortion refers to the condition in which all previous pregnancies have resulted in abortion. "Secondary" habitual abortion indicates that one or more previous pregnancies have proceeded beyond the 28th week.

The implantation was carried out as early in pregnancy as possible, in many cases as soon as the pregnancy test was positive or symptoms as well as a missed period made it reasonably certain that the patient was pregnant. The majority of patients received implants before the eighth week and almost all of them before the 10th week. Six 25-mg. pellets of progesterone were introduced beneath the deep fascia of the thigh by means of a trocar and cannula by the technique previously described (Bishop, 1949). No other treatment or precautionary regime was prescribed.

Results

TABLE II.—Results of Present Series (40 Cases)

No. of Successive Abortions Immediately Preceding the Treated Pregnancy	No. of Patients	Outcome of Treated Pregnancy		Percentage Successful Results
		Success	Failure	
A. <i>Primary Habitual Abortion</i>				
2	16	14	2	88
3	6	4	2	67
4 or more	6	3	3	50
B. <i>Secondary Habitual Abortion</i>				
2	9	7	2	78
3	2	1	1	} 67
4 or more	1 (6 miscarriages)	1	0	

A successful result is defined as one in which the pregnancy proceeded to 28 weeks, but in this series all the patients "successfully" treated, in fact, had live babies. One of the patients treated for primary habitual abortion who had had four or more previous abortions, and whose current pregnancy was unsuccessfully treated with progesterone-pellet implantation, had had more than 15 miscarriages. On the other hand, the successfully treated case of secondary habitual abortion with four or more previous abortions had actually had six sequential miscarriages since her previous full-term pregnancy.

Cases Not Included in the Series

One patient had had an eight-weeks miscarriage in July, 1939. In January, 1944, she had a full-term normal delivery, having been treated with progesterone injections during this

pregnancy. In August, 1945, there was an abortion at just over four months, and in March, 1946, a miscarriage occurred at six weeks. In both these pregnancies progesterone was administered by injection. In August, 1949, a live child was born following a pregnancy in which a progesterone implant was carried out by us at Chelsea Hospital for Women. The case was therefore included in our previous series. Since then the patient has had another live child, born in July, 1951, after a pregnancy which was again treated with an implant. Because of the previous successful pregnancy this case no longer falls under our definition of "secondary habitual abortion."

Four other cases are not included in this series because in each case the pregnancy immediately preceding that under consideration was one in which a progesterone implant had been administered, the pregnancy proceeding to a successful termination.

The following Table gives the combined results of the two series:

TABLE III.—Combined Results (85 Cases)

No. of Successive Abortions Immediately Preceding the Treated Pregnancy	No. of Patients	Outcome of Treated Pregnancy		Percentage Successful Results
		Success	Failure	
2	53	45	8	85
3	17	13	4	76
4 or more	15	10	5	67
				72

Discussion

The calculations most often quoted in estimating the "spontaneous cure rate" are those of Malpas (1938) and Eastman (1947). These are shown in Tables IV and V.

TABLE IV.—Malpas's Figures

No. of Previous Abortions	Spontaneous Cure Rate of a Subsequent Pregnancy
1	50 to 78%
2	9, 62%
3	7, 27%
4	0.3, 6%

TABLE V.—Eastman's Figures

No. of Cases	Previous Abortion	Will Abort from Accidental Causes	Will Abort from Recurrent Causes	Total Abortions	% Will Abort	Spontaneous Cure Rate
100,000	0	9,600	400	10,000	10.0	—
10,000	1	922 (9.6% of above figure)	400 (same 400)	1,322	13.2	86.8
1,322	2	88 (9.6% of above figure)	400 (same 400)	488	36.9	63.1
488	3	8 (9.6% of above figure)	400 (same 400)	408	83.6	16.4

It will be seen that our proportion of successful results for patients with a history of two previous abortions is 85%, whereas the spontaneous cure rate of Malpas and Eastman is in the region of 63%. It is, however, in groups in which three or more previous abortions have been recorded that the true definition of "habitual abortion" operates. Malpas calculates the expected spontaneous cure rate for three previous abortions at 7 to 27%, and for four at 0.3 to 6%. Eastman calculates the spontaneous cure rate for three previous abortions at 16%. Our figures for three previous abortions are 76%, and for more than three previous abortions 67%. The combined figure for a series of 32 treated cases having had three or more previous abortions is 72% successful results. This is significantly greater than the calculations of Malpas and Eastman. It is of the same order as the results of Smith (1948), who reported 60 patients with a history of three, four, or five previous abortions, of whom 46 (77%) were successfully treated with stilboestrol in doses increasing from 5 mg. daily at the sixth week to

115 mg. daily at the 35th week. We suggested in our previous paper that the essential therapeutic mechanism may have been the same in our series of cases as in that of Smith—namely, that we were providing extrinsically the progesterone which was intrinsically lacking in these cases of early habitual abortion, whereas Smith was stimulating, by means of extrinsically administered oestrogen, the secretion of placental hormones and especially progesterone.

It may be observed that the dose of progesterone administered by implantation appears to be small. It has not been easy to determine the rate of absorption of implanted progesterone, because the pellets are apt to extrude if implanted superficially. Bishop and Folley (1951) were able to study the rate of absorption of only four pellets of 50 mg. of progesterone implanted in female patients, and found that 40% of each pellet was absorbed in just over 40 days. This indicates, for what it is worth, that progesterone is one of the more rapidly absorbed hormones when administered by pellet implantation. Calculating from the findings of Bishop and Folley, we think it probable that the long cylindrical-shaped 25-mg. pellet which we have been using is fairly rapidly absorbed and may not remain effective for more than about a month. Nevertheless, if these early habitual abortions are due to a progesterone deficiency which operates during the second and third months of pregnancy, possibly by leading to an inadequate decidual reaction which endangers the safe embedding of the early ovum, administration of a constant though transient exogenous supply of progesterone by implantation may carry the patient over the critical period when abortion is mostly likely to occur.

One is of course always conscious of the possibility that the particular pregnancy under consideration may have gone to term without therapeutic aid. It is for this reason that we sought statistical advice both in regard to our original series and in respect of the present series. (Dr. Doll again is of the opinion that our results are of significance provided that the incidence of true habitual abortion is not much less than 0.1%.) One cannot, however, altogether exclude the psychological factor. Many habitual aborters and their husbands or relatives are highly strung and need reassurance that all will be well in the present pregnancy. Possibly the psychotherapeutic effect of an implant, as opposed to a series of injections or tablets by mouth, may in some cases supply the necessary confidence to enable the patient to retain the embryo during those early critical days.

Bevis (1951) has studied a series of 32 cases of habitual abortion (three or more previous abortions), of which 26 (81%) gave birth to live children. These patients received no treatment which we would regard as effective, though they were advised to rest at the time the menses would have been due. They were, however, submitted to elaborate investigation, including glucose-tolerance tests, estimation of basal metabolic rate, and fortnightly estimation of urinary pregnanediol. It is true that some of Bevis's cases did not come under observation until the 12th week of pregnancy—that is, when the early abortion hazard had been overcome. Nevertheless, if one is to accept his results at their face value—and we are in no position to say that one should not—and if one is also to agree with the calculations of Eastman and Malpas, one must logically conclude that 81 minus 16%—namely, 65%—of patients who have experienced more than three early abortions have done so for psychological reasons and that any procedure which is likely to gain their confidence may well prove successful. There is of course an obvious way of settling the question whether a progesterone implant is endocrinologically or merely psychologically therapeutic—namely, to treat alternate cases with implants of progesterone and an inert compound such as cholesterol.

We would, however, repeat the observation which we made in our first paper, that our results do not indicate that progesterone-pellet implantation in the dosage used is harmful in cases of habitual abortion.

Summary

A further series of 40 cases with a history of two or more miscarriages before the end of the fifth month of pregnancy, immediately preceding the treated pregnancy, were given an implantation of six 25-mg. pellets of progesterone.

Previously a series of 45 cases was reported upon. From this combined series of 85 cases 32 patients had experienced at least three miscarriages occurring before the end of the fifth month of pregnancy. Twenty-three patients (72%) produced live children during the current pregnancy in which the progesterone-pellet implantation was performed. This represents a significantly higher success rate than that expected from the calculations of Malpas and Eastman.

The results of Bevis (80% success rate with three or more previous miscarriages) in patients who received no effective endocrine therapy but were submitted to a series of elaborate investigations are discussed in the light of the possible psychotherapeutic effect of any procedure likely to gain the patient's confidence.

We should like to record our thanks to Dr. Richard Doll, of the Statistical Research Unit, Medical Research Council, for his interest and comments on this series of cases, and to members of the staff of Chelsea Hospital for Women and to other gynaecologists and doctors who have referred the patients in this series to us for implantation.

ACUTE POLYARTHRITIS WITH PULMONARY CONSOLIDATION AND PLEURAL EFFUSION

BY

A. W. LEES, MD., F.R.F.P.S., M.R.C.P.Ed., D.P.H.

Although numerous examples of "rheumatic pneumonia" and "rheumatic pleurisy" have been recorded, many observers are sceptical of the specific nature of these conditions, chiefly because in most reported cases severe cardiac damage has been present. The following cases are of interest because, although the probable diagnosis was acute rheumatism with pulmonary manifestations, no evidence of cardiac involvement could be detected, although eventually a mitral systolic murmur appeared in one.

Case 1

A man aged 37 was admitted to hospital on July 1, 1950, because of a rapid deterioration in his general condition. Fourteen days before admission his knee-joints had become painful, red, and swollen, and later his ankle-joints, wrists, interphalangeal joints, elbow-joints, and shoulder-joints became similarly affected. His health had been good until December, 1949, when he had rheumatic fever; he made a complete recovery and resumed work in February, 1950. His mother, aged 67, was crippled with rheumatoid arthritis.

On admission the wrists, interphalangeal joints, knees, and ankles were red, swollen, and extremely painful and tender, and the shoulder-joints and elbows were painful on movement. The skin was warm and moist. The patient appeared gravely ill; his colour was ashy-blue, he was slightly dyspnoeic at rest, and he had an anxious expression. His temperature was 100.4° F. (38° C.), pulse 108, and respirations 22. Over the lower lobe of the left lung the percussion note was dull, the respiratory murmur bronchial and loud, and the vocal resonance increased. Numerous medium moist crepitations could be heard over the left lower lobe. Clinical and electrocardiographic examination revealed no significant cardiac involvement at any stage. His general condition began to improve on July 5. A chest radiograph on July 7 revealed left basal consolidation with overlying pleural thickening or a small effusion. The heart was of normal size. Aspiration on July 10 produced 60 ml. of a sterile, straw-coloured fluid containing roughly equal numbers of polymorphs and lymphocytes; no tubercle bacilli were found on direct examination, culture, or guinea-pig inoculation. Signs of consolidation in the left lower lobe began to disappear on July 12, and a radiograph on the 14th showed that the condition had almost cleared up; crepitations were present, however, until August 11. Cough was slight throughout, and was always non-productive of sputum.

Calcium aspirin, 150 gr. (10 g.) daily, was given from July 1 to 9, but, although it relieved joint pains, the temperature did not settle, varying between 97 and 103° F. (36.1 and 39.4° C.). Penicillin, 600,000 units daily, was started on July 9, and the temperature, which had fallen on the previous day, settled, although there were subsequent minor elevations. Penicillin was stopped on July 18. After stopping the aspirin on July 9 the joints again became swollen and painful, and it was reinstituted on July 12, with marked benefit; it was finally discontinued on September 27. Blood examination on July 4 showed: R.B.C., 5,500,000; Hb, 90%; W.B.C., 7,000 (polymorphs 82%, lymphocytes 18%); no malaria parasites; and on July 8: W.B.C., 6,500 (polymorphs 78%, lymphocytes 20%, monocytes 2%); no malaria parasites. Blood cultures on July 10, 11, and 13 were negative.

A throat swab on July 6 was negative for *B. diphtheriae* and haemolytic streptococci; there was a predominant growth of *Str. viridans* and a light growth of pneumococci. Serological tests on serum taken on July 13 were negative for typhoid fever, paratyphoid A and B, brucellosis, and typhus. Serum taken on August 29 was tested at Colindale Virus Reference Laboratory; complement-fixation tests for influenza A and B, Q fever, and the psittacosis-L.G.V. (lymphogranuloma venereum) group were negative, and there was no significant agglutination of *Streptococcus M.G.* or significant titre of cold agglutinins. W.R. and gonococcal complement-fixation tests on July 6 were negative. The erythrocyte sedimentation rate (E.S.R.) on July 4 was 114 mm. in the first hour and 120 mm. in the second hour (Westergren method). The corresponding rates on July 10, 13, 24, and August 14 were 108 and 118, 90 and 98, 15 and 38, and 8 and 18 mm., respectively. A bronchogram on August 17 showed a normal left bronchial tree. The patient was discharged on October 14. He was well apart from occasional stiffness of the ankle-joints after exercise.

Comment.—The general aspect of the patient—cyanotic, dyspnoeic, and anxious, coupled with the arthritis—suggested bronchial carcinoma with mediastinal compression and joint manifestations, but the course of the illness ruled this out. Woodland (1947) and others have described cases of pulmonary tuberculosis with associated arthritis, but the clinical features made this diagnosis untenable, and investigation of the pleural fluid revealed no evidence of tuberculosis. There was no cough, sputum, pain in the side, or polymorphonuclear leucocytosis as in bacterial pneumonia. Because of the persistent crepitations at the left base an acute exacerbation of a mild bronchiectasis

was considered in spite of the absence of a suggestive previous history, but bronchography showed a normal bronchial tree. Serological investigations did not incriminate any of the virus or rickettsial groups tested. Certain fungi, especially coccidioidomycosis, may cause pulmonary lesions and arthritis; in endemic areas skin tests with specific antigen and complement-fixation tests are of diagnostic value, but they were not considered necessary in the present case. High antistreptolysin titres have been noted in rheumatic fever (Boisvert, 1940; Bunim and McEwen, 1940) and a rising titre of antistreptolysin is reported by some as of diagnostic value. Antistreptolysin titres were not ascertained in this case. The final diagnosis was acute rheumatism with rheumatic "pneumonia" and pleural effusion.

Case 2

An obese male schoolteacher aged 42 was admitted to hospital on March 1, 1951, with a diagnosis of acute rheumatism. Eight days before admission he felt "shivery" and experienced a sensation of stiffness in the shoulders, elbows, wrists, and right knee. The right knee subsequently became swollen and painful.

On admission his temperature was 98.4° F. (36.9° C.), pulse 90, and respirations 30. His blood pressure was 150/90. Examination revealed limitation of movement of the right hip and left elbow and shoulder, and reddening and tenderness over the first left metacarpo-phalangeal joint. The patient's mental state was peculiar; he prattled childishly in answer to questions, described past trifling ailments in great detail, and claimed that he was unable to sit up or move in bed. No evidence of organic disease of the nervous system could be found. Apart from the above findings, examination was essentially negative. The temperature rose to 100° F. (37.8° C.) on March 2 and remained elevated and swinging. There was profuse sweating. Blood examinations on March 2, 5, and 12 showed: W.B.C., 12,000–20,000; 90% polymorphs. Lumbar puncture on March 5 produced a clear fluid not under pressure; cells 2 per c.mm.; total protein, 26.4 mg. per 100 ml.; sugar, 65 mg. per 100 ml.

On March 8 numerous crepitations were heard over the left lower lobe and the percussion note was impaired. There was a slight productive cough, and culture of sputum yielded a moderate growth of *Staph. albus* and *Str. viridans*. A chest film on the same day was reported as showing left lower lobe consolidation. The appearances suggested that there might also be some overlying fluid, and although the physical signs indicated only consolidation, aspiration on March 12 produced half a pint (284 ml.) of straw-coloured fluid from the left thorax.

By March 21 crepitations could no longer be heard over the left lower lobe and the percussion note was resonant over the left lung, but examination revealed signs of a large right pleural effusion. Half a pint (284 ml.) of straw-coloured fluid was aspirated from the right thorax, though much more could have been removed. A chest x-ray film on March 23 showed clear lung fields and only a slight haziness in the right cardiophrenic angle.

Several therapeutic agents were administered: chloramphenicol, 500 mg. six-hourly, from March 4 to 22; penicillin, 300,000 units four-hourly, from March 8 to 13; and "sulphatriad," 1 g. four-hourly, from March 12 to 17. These drugs had no effect on the temperature, which swung between 100 and 102° F. (37.8 and 38.9° C.) and had no apparent effect on the migratory arthritis or mental upset, although these symptoms had improved somewhat by March 19. On March 22 sodium salicylate, 120 gr. (8 g.) daily, was started, and other medication discontinued. The temperature fell to normal on the 23rd and remained normal except for rises to 99° F. (37.2° C.) on March 31 and April 8, and the arthritis at once improved and soon cleared up. The mental upset speedily disappeared. The E.S.R., which was 90 mm. in the first hour and 114 mm. in the second hour on March 23, slowly fell. It was 75 and

98 mm. on March 30, 56 and 88 mm. on April 6, 60 and 80 mm. on April 13, and 15 and 45 mm. on April 27.

On April 6 a soft systolic murmur, best heard at the mitral area and at the lower left border of the sternum, was heard for the first time, and this murmur was still present on May 1. At the latter date the general condition of the patient was excellent. There was no evidence of cardiac insufficiency at any time.

The following investigations were negative: examination of the urine for blood, albumin, sugar, bile, cells, casts, and culture for organisms; blood culture on March 7, 8, and 16; W.R. and Kahn tests on March 2 and 14; culture of faeces for dysentery and typhoid groups on March 6; serological examination for typhoid, paratyphoid, and abortus on March 6 and 20; Schuffner test for *L. icterohaemorrhagiae* and *L. canicola* on March 8; sputum for tubercle bacilli on several occasions; direct examination and culture of pleural fluid for pyogenic organisms; direct examination, culture, and guinea-pig inoculation of pleural fluid for tubercle bacilli. The blood urea was within normal limits during the course of the illness. An electrocardiogram on April 27 showed no abnormality.

Comment.—As the patient had haematemesis from a duodenal ulcer in 1939 and again in 1948, and the chest x-ray film on March 8 showed a rather high left diaphragm, the underlying condition was thought to be either a left sub-phrenic abscess or a bronchial carcinoma with secondaries in the brain. The first diagnosis had to be abandoned when screening on March 14 showed that the diaphragmatic elevation was due merely to gas in the stomach and intestine, and the second diagnosis was disproved by the course of the illness.

Discussion

Broadly speaking, the cases of rheumatic, "pneumonia" reported fall into two main clinical groups, though many cases show features of both, and the pathology appears to be the same. In the first group the lower lobes, often the left, are affected, the consolidation is usually extensive, and its duration, though sometimes only a week or two, may be a matter of months. In the second group the consolidation tends to be focal, multilobular, evanescent, and migratory, though if the infection is severe the lungs may become so widely involved that death results.

Cheadle (1888), Naish (1928), Muirhead and Haley (1947), and Van Wijk (1948) have described cases which belong to the first group, and most of Rabinowitz's (1926) cases seem to come into this category. Examples of the second group of cases in which the consolidation tends to be focal and multilobular have been described (Coburn, 1933; Neuburger *et al.*, 1944; Griffith *et al.*, 1946; Jensen, 1946; Mossberger, 1947; Seldin *et al.*, 1947; Levy *et al.*, 1948; Gonzalez, 1949). In severe cases death ensued with widespread pulmonary involvement, but in milder cases the lesions tended to be migratory and ephemeral. Cough with a tenacious blood-stained sputum has been noted by several authors, including Paul (1928), Muirhead and Haley (1947), and Seldin *et al.* (1947), and the latter observers found the sputum on occasion contained frank blood. Griffith *et al.* (1946) found a blood-stained sputum in the severer cases. X-ray films showed cloudy opacities which tended to disappear and reappear in the same or other situations. Similar migratory opacities have been noted in asthma (Harkavy, 1941), angioneurotic oedema (Vaughan and Hawke, 1931; Cole and Korns, 1933), periarteritis nodosa (Weir, 1939; Elkeles, 1944), and in Löffler's syndrome (Löffler, 1932). Arthritis and pulmonary manifestations without evidence of carditis have been reported by Jensen (1946) and Van Wijk (1948).

Salicylate therapy appears to have little effect on the course of rheumatic "pneumonia." Cheadle (1888) and Seldin *et al.* (1947) stated that pyrexia was unaffected by salicylates, though Naish (1928) mentioned that in cases receiving salicylates there was little rise in temperature.

Levy *et al.* (1948) found that neither salicylates nor penicillin had any effect. Some observers have considered that the pathological changes may be due to congestion as a result of heart failure, but Epstein and Greenspan (1941) did not find the characteristic, if non-specific, pathological picture in the lungs of patients dying with pulmonary congestion as a result of hypertension, coronary thrombosis, or mitral stenosis without active rheumatic infection. Gregory and Rich (1946), by injecting rabbits with foreign protein, were able to produce changes in the lung similar to those seen in "rheumatic pneumonia." They considered that an anaphylactic angitis affecting mainly the capillaries is the essential lesion in the rheumatic lung, and that all the other findings can be explained on this basis.

In interpreting the pathological changes found in the lungs in acute rheumatism observers have differed in their estimation of the part played by cardiac insufficiency, many believing that this is the principal factor. Cases of rheumatic fever showing arthritis and pulmonary manifestations without carditis are therefore of interest, though in the absence of a specific test it is then difficult to be certain of the diagnosis of rheumatic fever. The first case described here falls into this category, and, although cardiac involvement was eventually detected in the second, there was never evidence of failure. Pulmonary manifestations in rheumatic fever may be very misleading; Griffith *et al.* (1946) state that some of their cases were diagnosed as "atypical pneumonia" until cardiac involvement became apparent.

My thanks are due to Dr. James McIntosh, consultant physician, Western District Hospital, Glasgow, for permission to publish these cases, and to the resident medical officers who assisted with investigations.

K. Hellmann, of the M.R.C. Climatic and Working Efficiency Unit, raises an interesting physiological point in a recent issue of *Nature* (January 19, p. 113). As is well known, the sweat glands of the skin receive an innervation from the sympathetic nervous system, but, unlike other organs under sympathetic control, are not brought into action also by adrenaline but only by pilocarpine and acetylcholine; and they are inhibited by atropine. Hellmann has been studying the cholinesterase of the sweat glands in the pad of the cat's foot by a series of histochemical tests which enable him to display the distribution of enzyme activity throughout a tissue section, and to define the enzyme's specificity of action. He finds that the enzyme is present in the terminal nerve fibres, and disappears when these degenerate, and also that its specificity differs from that of the true cholinesterases hitherto found in nerve fibres, which specialize in the hydrolysis of acetylcholine. This leads him to suggest that the sympathetic cholinergic transmitter may not be acetylcholine after all, but some allied substance.

THE DURATION OF THE ACTION OF DIFFERENT INSULINS

BY

F. GERRITZEN, M.D.

(From the Department of Endocrinology and Diseases of Metabolism, Medical Service, University Hospital, Leyden, Holland)

This investigation was undertaken to compare the different insulins under the same experimental conditions, and to ascertain the duration and, if necessary, the character of the action of new insulins brought on the market. The textbooks on insulin do not supply any data on the duration of action (Grevnstuk and Laqueur, 1925; Hill and Howitt, 1936; Geiling *et al.*, 1937; Jensen, 1938; Joslin, 1946).

Experimental Method

The experimental conditions are of great importance. In the first place, it would seem desirable to investigate the action of insulin in human beings, and so avoid the necessity of adapting the results obtained with test animals. Besides, the experimental conditions of this investigation would not be suitable for animals. It would, of course, have been advisable to use diabetic patients, but for various reasons this was not possible.

The subjects were young healthy student volunteers, whose blood sugar was investigated under standardized conditions, as follows. They were asked to lie down from 11 p.m. the night before—that is, seven hours previous to the experiment—and also during the experiment, in order to eliminate the influence of exercise on the blood sugar. From 6 a.m. onward on the day of the experiment they ate 50 g. of mashed potatoes (about 10 g. of carbohydrate) and drank 30 ml. of water every hour, until the experiment was finished—that is, until the average blood sugar had returned to its original level. Every hour the blood sugar was determined according to the Hagedorn-Jensen method. The values at 7 a.m. and 8 a.m. were used as a starting-point. At 8 a.m. 20 units of insulin was injected subcutaneously, a different brand of insulin being given to each group of test persons. One group which did not receive any insulin served as controls.

In all, 10 different insulins were tested. The accompanying Chart shows the number of persons in each group from whom the average was calculated. This method was chosen because it eliminates all other factors which might influence the blood-sugar level (Himsworth, 1934; Martin *et al.*, 1940). As fasting might decrease the blood sugar, food to a standardized amount was given each hour, to prevent the rise in blood-sugar level which would occur with a larger food intake and which might simulate the end of the action of the insulin. On this matter Peck (1942) states: "There have been only a few published reports of clinical investigations of protamine-zinc insulin which have taken advantage of the invaluable procedure of measuring the rate of insulin action against a known constant carbohydrate intake."

With the present method one finds a constant average blood-sugar level in healthy people, so that any decrease of this level may be attributed to the insulin. If diabetic patients are examined under these conditions a 24-hour rhythm is found in the blood sugar (Gerritzen, 1942). This makes it very difficult, if not impossible, to judge whether the decrease is in consequence of the 24-hour rhythm or whether it should be attributed to insulin. Besides, it is impossible to find enough diabetic subjects in whom to calculate the average blood-sugar level after the administration of insulin.

The hourly intake of 10 g. of carbohydrate diminishes the hypoglycaemia, and this would meet the objection that

Chart showing duration of action of various insulins.

with a strong decrease of the blood sugar a regulating mechanism, with adrenaline as its principal component (Drury and Greeley, 1939), might become active and thus render evaluation of the action of insulin impossible. During my experiments only minor hypoglycaemic symptoms occurred, and, as expected, without any close relation to the level of the blood sugar.

In addition to the duration of action of equal doses (20 units) of various insulins, it was my intention to find out whether there were any differences in the character of their action (de Jongh, 1924). While assuming that the resorption of insulin in diabetic persons does not in any way differ from that in normal individuals, I think that the differences in action in the latter may also apply to diabetics. In other words, that the order of succession in the duration of the action, as demonstrated in this experiment with healthy

individuals, may also be supposed to exist in diabetic patients. It is obvious, of course, that the actual figures characterizing the duration of the action of insulin in this experiment need not apply to diabetics. However, if, under the conditions of this experiment, it is found that regular insulin is effective for eight hours, this result would agree fairly well with the data in the literature (Scott and Dotti, 1932; Lawrence, 1938; Martin *et al.*, 1940; Peck, 1942; Colwell, 1947), and one would not be far out in accepting the figures as applying to diabetics.

Results

In the control group no significant deviation was found between the average blood sugar values at different hours. There was a significant deviation between the blood-sugar values of the different test persons, calculated according to the F-test (Davies, 1949), the standard error of which was 6.9 units if the blood-sugar values are expressed in percentages to the third place of decimals. In the group receiving insulin there was no significant increase of this standard error in comparison with the control group.*

Control Group.—The average blood-sugar level does not show any oscillations, and may be considered constant.

Regular Insulin (Organon).—The blood sugar reaches its lowest point after one hour and returns to its starting point in eight hours.

Protamine-zinc Insulin (Organon).—Contrary to the many data in the literature, I find for P.Z.I. a duration of action of 18 hours. No evidence was found of a duration of 48 hours or longer. The lowest point is reached in five to eight hours.

Di-insulin (Novo).—Duration of action, 16 hours. The greatest decrease in blood sugar is during the first three hours.

Iso-insulin (Novo).—Duration of action 17 hours. Rapid decrease of sugar in the first hour. The steep decrease within the first hour leads to the assumption that this preparation contains regular insulin, but, according to Hallas Möller, this is not the case.

Globin Insulin (Burroughs Wellcome).—Action is identical with that of di-insulin.

(1) **N.P.H. 50 (Organon).**—Duration of action, 11 hours. Lowest point after four hours.

(2) **N.P.H. 50 (Lilly).**—Duration of action, 11 hours. Lowest point after three hours.

Insulin Mixtures (Organon).—The impression is gained that the duration of action of the mixture depends on the regular insulin content only so far as the decrease during the first three hours is greatest with the mixture containing most regular insulin—the 3:1 mixture—and that thereafter the blood sugar takes longer to come back to the starting-point than with the 2:1 and the 1:1 mixtures. This would explain the longer duration of the action with a higher regular insulin content.

I am indebted to Miss S. P. I. Hoogeveen for the accurate blood-sugar determinations, and to Mr. F. H. Stieltjes for the statistical calculations. I am grateful also to the 64 students who voluntarily served as test subjects. This experiment was made possible by a grant from Messrs. Burroughs Wellcome and Co.

*An analysis of variance is effected with the control group, globin insulin 1:1 mixture, 2:1 mixture, and 3:1 mixture according to Fisher (1937). The χ^2 test (Bartlett test 3), applied to all error variances, showed that the inclusion of the 1:1 mixture in the calculations led to very uncertain results; otherwise this experiment had a very low error variance. The χ^2 test was employed to find whether there was an individual variance of reaction to insulin, as this would only result in an increase of the error variance. There remains, therefore, a reasonable chance that there are no individual differences of reaction to insulin. This implies that there is a reasonable possibility that, by increasing the number of test persons, more definite results might be obtained.

TREATMENT OF HYPERTENSION BY ORAL METHONIUM COMPOUNDS

BY

A. J. M. CAMPBELL, M.B., F.R.F.P.S.*Medical Registrar, Royal Alexandra Infirmary, Paisley***J. GIBSON GRAHAM, M.D., F.R.F.P.S.***Senior Physician, Royal Alexandra Infirmary, Paisley;
Associate Physician, Western Infirmary, Glasgow*

AND

R. D. H. MAXWELL, M.B., Ch.B., B.Sc.*May and Baker, Ltd.*

For almost two years we have used methonium compounds in the treatment of hypertension, and during this time have examined their action upon nearly 100 patients, of whom a fair cross-section have been followed up and observed in detail.

Hexamethonium, pentamethonium, and hexamethylene bis-dimethylethyl ammonium ("M. & B. 1863") in bromide, chloride, iodide, and tartrate salts have been used. Our chief aim has been to establish, where possible, control of the hypertension and relief of symptoms mainly by the oral dosage of one of these compounds.

Since the original clinical investigations of the effect of pentamethonium and hexamethonium upon the cardiovascular system (Arnold and Rosenheim, 1949; Arnold, Goetz, and Rosenheim, 1949), a series of reports have appeared upon their therapeutic application. Smirk and Alstad (1951), giving these drugs chiefly parenterally, have described the precise control of pressure which is obtainable. Saville (1950), Turner (1950), and Mackey and Shaw (1951b), together with Campbell and Robertson (1950), have, with oral administration, obtained a reasonable depression of the blood pressure of many of their cases, accompanied by a clinical improvement comparable at times to that seen when the drug is given parenterally. The action is much less constant and less apparent when assessed by the effect upon the pressure, and Locket, Swann, and Grieve (1951) have recorded that in their series there was little effect upon the pressure of out-patients.

We have treated hypertensive patients with methonium compounds when their response to dietary limitation and sedation was unsatisfactory, and by careful examination have excluded patients with hypertension of remedial origin. Renal disease was not regarded as a contraindication, and several cases of chronic nephritis with hypertension and severe symptoms were treated.

It is known that most patients with hypertension may be maintained symptom-free by severe dietary restriction and sedation in hospital, but it is equally recognized that often when these patients return home or to work there follows a reversal of improvement both in symptoms and in blood pressure. In the absence of any treatment of the underlying cause of the hypertension there is every indication for an out-patient therapeutic measure which would enable these patients to be maintained in reasonably good health, with an arrest of progress of their symptoms and signs.

We gave methonium compounds intravenously, intramuscularly, subcutaneously, and orally, and tended to use parenteral routes for investigation and the oral route for treatment. Latterly we employed combined oral and subcutaneous administration when the pressure response to oral administration was unsatisfactory. Parenteral dosage consisted in the cautious administration of 10–15 mg. of hexamethonium bromide initially, with increase in quantity and frequency until up to 300 mg. in divided doses was given daily. Oral dosage begins with a single tablet, followed by a progressive increase in frequency and quantity to a maximum of 12–16 tablets a day. Tablets of comparable methonium content were used—that is, a 250-mg. tablet of hexamethonium bromide, which is equivalent to a 350-mg. tablet of the bitartrate and to 125 mg. of M. & B. 1863 bromide.

At no time was more than 4 g. of hexamethonium bromide given daily, as activity is not proportional to dosage beyond this level, other than a possible local effect upon the bowel. Clinical results are tabulated in three groups.

1. Essential Hypertension

This group comprised most of our cases, their ages ranging from 29 to 67 years. All had a diastolic pressure above 115 mm. Hg. Of these patients 35 who could conveniently attend for regular examination were observed at short intervals for a period of 4–18 months, the average duration of treatment being 12 months. Hexamethonium was used in 25 and M. & B. 1863 in 10, in both bromide and bitartrate salts.

In every case methonium treatment was preceded by at least 14 days' rest in bed, with sedation and dietary limitation. Cases were selected for treatment only when the response was either disappointing or absent.

Effect upon Signs and Symptoms

The incidence of the signs and symptoms of 16 male and 19 female patients with essential hypertension are reproduced in Table I.

Results are expressed by the classification of Wagener and Keith (1939), which is a clinical assessment and is also of some prognostic value.

TABLE I

TABLE II.—Number in Each Group by the Classification of Wagener and Keith Before and After Treatment

Group	Before Treatment	After Treatment
I	—	1
II	2	23
III	29	10
IV	4	1

Table II shows the change in grading after treatment—that is, a marked reduction in symptoms and signs. Clinical improvement was obtained in 23 out of 35 cases, with results

similar to those recorded by Smirk and Alstad (1951). Most striking was the relief of headache, and this could be obtained in some patients with a dosage too low to influence systemic blood pressure. Regression of papilloedema, when present, and organization of exudates and haemorrhages were noted. Dyspnoea was markedly reduced, and over a period of months reduction in size of the heart was seen when enlargement was present before treatment. The most remarkable effect was the return of most of these patients to a state of normal activity, either to work or to domestic duties. There were a number of failures. Two young adults with a symptomless hypertension were treated prophylactically without producing a fall in pressure. One patient developed a hypertensive encephalopathy during treatment, and in another two cases there was a possible extension of a recent cerebral thrombosis. One patient with severe headaches and a previous cerebral thrombosis had no relief of headache despite a satisfactory fall in pressure.

Effect upon the Blood Pressure

The assessment of the long-term effect of hexamethonium on the blood pressure is difficult. We found that in many

FIG. 1.—Typical response of blood pressure to M. & B. 1863.

cases it is possible to produce by oral and by parenteral administration of the methonium compounds a fall much greater than is seen during rest in bed alone, and this fall bears no relation to that obtainable during profound sedation such as the sodium amytal test. When these drugs were used parenterally it was possible to obtain low levels of pressure, as Smirk and Alstad (1951) have described. Treatment was mainly by the oral route, which differs from parenteral administration in that the response is much slower, single doses producing a much less definite effect. It is generally necessary to administer the drugs for several days, during which time a fall in the pressure is observed in favourable cases, either beginning immediately or after several days, suggesting a cumulative effect. During this initial period of treatment one-third of the patients had diastolic pressures of under 100 mm. In a further one-third the effect upon the pressure, while considerable, was not so pronounced, and in the remaining one-third the systolic and diastolic pressures fell less than 20 mm. The fall was generally greater in the systolic than in the diastolic pressure. An increase of dosage does not produce any greater response, but the addition of parenteral administration was usually effective in producing lower pressure levels.

The maximum effect is found about the seventh to fourteenth day of treatment. A typical response is recorded in Fig. 1.

The blood pressures of out-patients show an initial progressive rise, and the drug loses some of the original effective-

ness during the first weeks of treatment. Subsequently tolerance does not appear to increase for a period of one to two months, and this not in all patients. Tolerance developed more rapidly to M. & B. 1863 than to the other compounds. Withdrawal of treatment for a period of a few weeks or less is usually followed by some loss of this tolerance, and resumption must be cautious. While tolerance to pentamethonium and hexamethonium was interchangeable, this did not always apply to tolerance developed to M. & B. 1863 and hexamethonium. Locket, Swann, and Grieve (1951) have attributed much of the effect upon pressure to the high concomitant dosage of bromide. In six cases we substituted for hexamethonium bromide similar tablets of potassium bromide with the same bromide ion content, and found a steady rise in pressure and recurrence of symptoms identical with results obtained by drug withdrawal. Further, hexamethonium bitartrate was found to be as effective therapeutically as hexamethonium bromide.

Fig. 2 shows the effect of hexamethonium bromide and bitartrate upon the blood pressure.

FIG. 2.—Effect of hexamethonium bromide and bitartrate on blood pressure.

2. Chronic Nephritis

Table III records the effect of hexamethonium bromide upon five patients with chronic nephritis with marked hypertension, impairment of renal function, and fundal changes. In each case some reduction of pressure has been possible, with good alleviation of symptoms and signs. Poor renal function in these cases was not a contraindication to treatment. Renal pathology, however, was unaltered, and two of these patients died during treatment—one from cardiac failure and the other from uraemia.

3. Malignant Hypertension

Two young patients with progressive hypertension and grave signs and symptoms were treated, their initial progress having been recorded previously by Campbell and Robertson (1950).

Case 1.—A married woman aged 22 was found in the third month of her pregnancy to have marked hypertension, which was unaltered when pregnancy was terminated at the

TABLE III

Age and Sex	Before Treatment			Treatment with Hexamethonium

15 F. ..	230/130	"	Severe	2	1010	1010	130	180/110	2.5	"	"

fifth month owing to a steady rise in pressure, with dimness of vision and increasing headaches. During the subsequent three months in hospital her condition deteriorated, with increasing blood pressure and the appearance of albuminuria, and the prognosis seemed to be very poor. Hexamethonium bromide in an average daily dosage of 2 g. was administered for six weeks, producing a fall in pressure from 220/135 to 140/90, with disappearance of headaches, visual improvement to normal, and regression of fundal changes from grade IV to grade II. During the past year she has been keeping house and leading a full life with no treatment whatsoever. However, during this period her albuminuria has tended to increase and her blood pressure rose steadily, reaching 180/105, so we decided to make a further attempt to modify her blood pressure. Marked sensitivity to hexamethonium was found, and, because of hypertensive vertigo, continuous administration does not appear at present to be advisable. It seems likely that the course of the disease has been modified, and that she has been given a useful extension of life.

Case 2.—This patient was a man aged 30, whose early treatment has previously been described. Subsequent progress was less favourable in that there was no arrest of his progressive renal lesion, but his general condition before death, which occurred eight months after the beginning of treatment, was good enough to permit of his discharge and even return to employment. Death was occasioned by uraemia, and the post-mortem findings were those of malignant hypertension.

Side-effects and Toxicity

The unselective action of the methonium compounds in producing a generalized interruption of the autonomic nervous system entails effects other than upon the blood pressure. Reference to this in the production of constipation and paralytic ileus has been made in the literature, particularly by Campbell and Robertson (1950), Bourne and Hosford (1951), and Mackey and Shaw (1951a), and transient effects upon accommodation and salivation have been described. The side-effects of M. & B. 1863 have not been significantly different in any respect.

No abnormal sensitivity to the initial dosage of methonium compounds orally was encountered, but early in our work two sudden circulatory collapses followed 100 mg. of hexamethonium bromide parenterally as a first dose.

During the earlier part of this investigation two patients developed bromide rashes and one-third of those treated had bromide retention accompanied by drowsiness, fatigue, depression, and muscular weakness. Substitution of the bitartrate of chloride salts resulted in the disappearance of these symptoms with no diminution of therapeutic response, as already recorded by Campbell and Robertson (1951).

Overdosage of one of the methonium compounds produced a circulatory collapse.

A woman aged 59 had a blood pressure of 210/170 when first seen, and this pressure fell to 220/120 after four weeks in bed. She had severe symptoms of hypertension, and treatment with hexamethonium bromide in amounts up to 2 g. a day produced a fall in her pressure to 115/95. She was sent home to attend as an out-patient, and during the next two months the average levels of pressure were 160/100. She was readmitted comatose with a pressure of 55/30, probably due to a gross self-administered overdosage. The response to continuous adrenaline infusion was transient and death ensued in a few hours.

Discussion

Our experience of the clinical application of the methonium compounds in hypertension accords with the early observations reported from this unit (Campbell and Robertson, 1950) and with the observations of Turner (1950), Saville (1950), and Mackey and Shaw (1951b). It has been possible to alleviate or to remove symptoms and to effect a disappearance or marked regression of physical signs, resulting in

reasonable health, compatible in most cases with the patient's return to useful activity and employment. No limitation has been imposed by age or severity of illness.

We are particularly interested to note that our clinical results were very similar to those obtained by Smirk and Alstad (1951), who used a more elaborate method of parenteral administration to obtain continuously lower levels of pressure than we sought. In fact, in our series we found that reduction of pressure to even 140/90 was not always well tolerated by patients who had a long history of hypertension. They complained of listlessness and fatigue.

Previous observations have been in general agreement in regard to the clinical improvements obtainable by oral dosage, but Locket, Swann, and Grieve (1951) have not reproduced the effects upon the blood pressure described. We have observed that, during treatment, blood pressures are very labile in many patients—downwards in response to erect posture and upwards in response to emotion and anxiety. Paton (1951) has noted the difference between the effect of methonium compounds and sympathectomy, the former blocking both the sympathetic and the parasympathetic components of the autonomic nervous system, so that there is a paralysis of the compensating mechanisms which normally maintain the constancy of the blood pressure; and procedures and drugs affecting the blood pressure will produce an exaggerated response. We have found it necessary to allocate a definite weekly time of attendance at the wards, where pressures are taken regularly by the hospital staff, who are known to the patients, in circumstances providing a reasonable period of observation. Failure to observe these precautions may have led to the disappointing results obtained by some workers, in direct contrast to the pressure records made during the careful and prolonged investigation by Mackey and Shaw (1951b).

Smirk and Alstad (1951) have declared that the optimum therapy in hypertension is the establishment of low levels of pressure; and Platt and Stanbury (1950), in the assessment of sympathectomy, have used as their criterion a fall of 20 mm. in the basal diastolic pressure. We have attempted rather to obtain a moderate but definite reduction over a long period in the blood pressure of these patients compared with their pressure when first seen. White, Dimond, and Williams (1950) have surveyed the morbidity and mortality over a three-year period among 100 patients with hypertension, half of whom had been subjected to sympathectomy. They found a much higher morbidity in the control series, and at the end of three years 16% of the sympathectomized patients were dead, as compared with 58% of the controls. They point out that this is more impressive evidence of the beneficial effect of this therapeutic measure in certain cases than is the usual method of studying the effect on blood pressure alone in cases in which important complications do not exist.

Ellis (1942) has emphasized that hypertension in itself does not constitute in general a serious limitation to life expectancy, but, once signs and symptoms develop, a threshold has presumably been exceeded and the prognosis is altered.

From experience with hexamethonium administered orally it seems possible that a rather lower average of pressure, with relief of symptoms and some regression of signs, may enable a proportion of hypertensive patients to return to this asymptomatic category with its more favourable prognosis. Keith, Wagener, and Barker (1938) have examined the life expectation of patients with hypertension grouped in the categories we have used, and find that 30% of group I, 42% of group II, 78% of group III, and 98% of group IV do not survive four years. Most of our patients have fallen within group III, and in up to two years of continuous observations there have been no deaths other than the one occasioned by overdosage.

Summary

Methonium compounds have been in use for up to two years, and the treatment of an unselected group of

35 patients with hypertension and severe symptoms and signs is described. These compounds were used orally with variable results upon the blood pressure, but in 23 of the 35 patients there was a good symptomatic improvement with regression of the signs.

Hexamethonium also produced a symptomatic improvement in five patients with severe chronic nephritis and two with malignant hypertension.

We are grateful to Dr. E. Robertson for his work during the early part of this trial and to other members of the hospital staff for their assistance. Mr. E. J. Baines, of the New Products Division of May & Baker Ltd., kindly made available the supplies of the compounds used.

Late Registrar, Obstetric Unit

Oldchurch Hospital, Romford, Essex

Following work by Paton and Zaimis (1949), Organe, Paton, and Zaimis (1949), and Arnold and Rosenheim (1949), pentamethonium and hexamethonium compounds have been used for the investigation and treatment of hypertension and peptic ulceration (Kay and Smith, 1950, 1951). It has been the experience of some (Freeman, 1950; Locket, Swann, and Grieve, 1951; Banton, 1951) that the oral administration of these in hypertension may fail to produce and maintain a lower blood pressure. Smirk (1950, 1951) and Frankel (1951) have suggested that, therapeutically, hexamethonium bromide should be given subcutaneously, much as insulin is given, the patient being instructed to inject an appropriate dose once or twice daily, or even more frequently.

Bromidism (Rosenheim, 1951; Holt and Litchfield, 1951; Locket *et al.*, 1951; Campbell and Robertson, 1951; Sommerville and Allan, 1951), cerebral thrombosis (Locket *et al.*, 1951; C. F. J. Cropper, 1951, personal communication), coronary thrombosis and death (Hirson

and Kelsall, 1951; Locket *et al.*, 1951) have been recorded with these drugs, and in our opinion injection by the patient himself in doses adequate to produce any fall in blood pressure can be an extremely dangerous procedure.

In a previous paper (Locket *et al.*, 1951) we expressed the view that much of the subjective improvement recorded in these patients was due to sedation, reassurance and its consequent relief of anxiety, and possibly other measures instituted, such as a salt-free diet. We did not feel, in view of the natural history of essential hypertension, that any of the symptomatic improvement could reasonably be attributed to the oral administration of the methonium compounds when used by us. Ayman (1930) pointed out that all methods of treatment of hypertension have in common the "enthusiastic treatment of a worried patient," and to this he attributed most of their success.

Through the good offices of Dr. R. Forgan, Messrs. May and Baker Ltd. have kindly provided us with a supply of hexamethonium bitartrate, and also an analogue of hexamethonium known at the moment as "M. & B. 1863." The chemistry of this new compound and related derivatives is described by Barber and Gaimster (1951) and the pharmacology by Wien and Mason (1951). It was originally issued as the bromide salt, but now as the bitartrate. Experimentally it is two to four times as active as hexamethonium bromide (C6) as a ganglion-blocking agent, and therefore might be expected to work in smaller dosage by mouth, with possibly a more sustained action. The formulae given below show the relation between M. & B. 1863 and C6.

For our trials M. & B. 1863 was issued in tablets of 125 mg. of the bromide or 175 mg. of the bitartrate, for oral use only; it was also available in solution for injection.

Most patients have received the drug by mouth only, but a few have had increasing subcutaneous or intramuscular injections of hexamethonium bromide or M. & B. 1863. After 48 hours these have been given oral M. & B. 1863. The dose of this compound was increased until a fall in blood pressure occurred or side-effects prevented any further increase. Most of our cases received no M. & B. 1863 from midnight to 6 a.m.

This communication is mainly based on a detailed analysis of our results in the treatment of 14 patients, both as in-patients and as out-patients. Since completing this review, however, we have also given M. & B. 1863 to many others, both as in-patients and as out-patients. We do not feel that these later results have differed in any way from those obtained in the 14 recorded cases. In all we have used the drug in more than 40 cases.

These results and conclusions relate to the long-term treatment of hypertension. We have found that a small intravenous dose (5 mg. of M. & B. 1863) will produce a most dramatic amelioration of dyspnoea in pulmonary oedema and "cardiac asthma" due to left ventricular failure in hypertension (not associated with coronary thrombosis). The results in some cases were infinitely better than when

using morphine and oxygen, and also were more sustained. So-called hypertensive encephalopathy, however, did not respond to this treatment (see for example Case 3 in this paper). This emergency use of the drug is not discussed further here.

The group of 14 patients is made up of two cases of severe rapidly progressive hypertension (albuminuria, papilloedema, slight diminution in renal function), one case of severe hypertension and papilloedema of at least five years' duration, three cases of chronic nephritis with high or very high diastolic pressure, a case of essential hypertension with superimposed toxæmia of pregnancy, and seven cases of essential hypertension with severe subjective symptoms, one associated with diabetes mellitus and hypertensive encephalopathy and the others with recurrent attacks of left ventricular failure and/or hypertensive encephalopathy. All these 14 patients had diastolic pressures of over 120 mm. Hg when treatment was begun, and all but three had diastolic pressures over 150 mm. Hg; in several cases the diastolic pressure frequently exceeded 180 mm. Hg.

Details are given of four of these cases, as they seem to be of particular interest.

Case 2

A married woman aged 39 had had essential hypertension for many years, with three stillbirths due to superimposed toxæmia of pregnancy. When she became pregnant for the fourth time she was given injections of pentamethonium bromide (C5) at six weeks, and later put on to oral C5. During the middle trimester of pregnancy her blood pressure fell to normal levels, but at the seventh month hypertension reappeared. The oral C5 was increased with no effect on her hypertension. She was then—when her blood pressure had risen to 190/130—given oral M. & B. 1863, and the dose was rapidly increased until she was receiving 250 mg. every one and a half hours. She felt very well, but her blood pressure steadily rose. The foetus was apparently very small for the state of pregnancy.

In spite of increasing doses of M. & B. 1863, and after a further week of treatment, the foetus died. The patient's high blood pressure was maintained for 48 hours until delivery of the macerated foetus and placenta occurred, and it then fell to the previous hypertensive level. At no time did the serum bromide exceed 50 mg. per 100 ml. There was no papilloedema at any stage, and the patient at all times felt very fit and well. During the last six weeks of her illness she remained in bed.

Comment.—In this case it is interesting to note the physiological fall in blood pressure in the middle trimester of pregnancy, and the failure of injected and oral C5 and oral M. & B. 1863 to keep the blood pressure within normal limits. (See accompanying Graph.)

Blood-pressure record of Case 2. (1) On admission to hospital, complete rest in bed. (2) Pentamethonium bromide started. (3) Patient discharged to antenatal clinic on pentamethonium bromide. (4) Readmitted to hospital, complete rest in bed. (5) M. & B. 1863 started. (6) Foetal death in utero.

The marked tendency of the blood pressure to fall in the middle trimester of pregnancy in the normal and hypertensive patients (Hare and Karn, 1929; Reid and Teel, 1939; Chesley, Annitto, and Jarvis, 1947; Browne, 1947) and in pregnant hypertensive animals (Page and Ogden, 1939) is quite well known, but we feel it should be emphasized in view of the use of the methonium compounds.

Case 3

A married woman aged 40, one of three cases developing definite papilloedema and albuminuria while receiving hexamethonium bromide or M. & B. 1863 orally, developed recurrent attacks of paroxysmal nocturnal dyspnoea and hypertensive encephalopathy while taking 4 g. of hexamethonium bromide daily. At this time her blood pressure, when she attended the out-patient department, was found to be 260+/180 mm. Hg, and she was immediately readmitted to hospital. After 48 hours of subcutaneous hexamethonium at two-hourly intervals she was given oral M. & B. 1863, and eventually received 250 mg. three-hourly. She was then allowed up. Her blood-pressure level persisted at 180–200/120 mm. Hg, and except for slight episodes of giddiness she felt relatively well.

In the out-patient department two weeks later her blood pressure was 260+/160 mm. Hg, but she felt very well. However, during the 48 hours before attending she had had a recurrence of occipital headache. Intractable constipation alternating with bouts of diarrhoea had been very troublesome. She still had albuminuria and papilloedema and a presystolic gallop. After some weeks her condition began to deteriorate, with no change in her blood pressure, though the dose was increased to 375 mg. seven times daily. She was readmitted in coma with a diastolic pressure averaging 180 mm. Hg, and, though a fall in her blood pressure was produced by intravenous M. & B. 1863, she died 36 hours after admission. In spite of papilloedema, albuminuria, and some diminished renal function, necropsy revealed arteriosclerosis but no evidence of malignant hypertension.

Case 4

A man aged 60 developed papilloedema, albuminuria, and a higher diastolic pressure (160 to 190 mm. Hg) while receiving 8–10 g. of hexamethonium bromide daily. There was no improvement in his condition at all to increasing doses of M. & B. 1863, and his average blood pressure was actually higher on that drug than it was without it.

Case 6

A married woman aged 35 had active chronic nephritis and severe menorrhagia. Her blood urea was 137 mg. per 100 ml.; standard urea clearance, 20–28% of average normal; urine albumin, 2–4 parts per litre; haemoglobin, 47%; blood pressure, 240–260/130–140 mm. Hg. M. & B. 1863, 125 mg. four-hourly, produced anorexia, nausea, and vomiting, but the diastolic blood-pressure level appeared to have been reduced by 20 mm. Hg. The dose was reduced with relief of her symptoms. The blood pressure did not rise. The urea clearance showed a steady fall, the albuminuria remained constant, and the blood urea rose to more than 270 mg. per 100 ml.

The patient's condition continued to deteriorate slowly, though with cessation of her menorrhagia the haemoglobin increased to 70%. The drug was then discontinued, and during the next six weeks her urea clearance rose by about 10% and her blood urea fell by more than 100 mg. per 100 ml. After a further month, during which she apparently remained fit, her blood urea began to rise again, and two months later she died in uraemic coma. Necropsy revealed chronic nephritis.

Discussion and Review of Results

In this series we did not meet with any case of bromide intoxication or bromide rash. The serum bromide level did not exceed 60 mg. in any case receiving the bromide salt.

Severe constipation was a more pronounced feature than in our past experience with pentamethonium and hexamethonium bromide and hexamethonium bitartrate. However, three patients attending the out-patients department complained of diarrhoea, which would follow several days' intractable constipation. Nausea and vomiting were complained of in six cases and were severe enough to necessitate a reduction in dosage in four cases.

In three patients the mean blood pressure was actually higher whilst the drug was being taken, and in many cases higher peaks of diastolic pressure occurred than during the control period. Increase in lability of the blood pressure was very marked. It was, however, difficult to decide whether this was due to the drug or was a normal feature of the disease.

One patient whose diastolic pressure rose to 170 mm. Hg on 2.0 mg. of M. & B. 1863 three-hourly showed a marked fall when given 250 mg. two-hourly. This fall was associated with gross deterioration in his physical condition and sense of well-being. A spontaneous thrombosis of his axillary artery developed. At this period he had a prothrombin time of 22 seconds (control, 13.5 seconds). Discontinuation of the drug relieved his general malaise, and his blood pressure rapidly rose to its previous level, but in a few days he had obvious congestive heart failure. Routine treatment of his heart failure eventually resulted in great improvement and a "maintained fall in blood pressure." Repeated electrocardiograms, including full unipolar chest leads, showed no evidence of coronary thrombosis, his blood culture was negative, and neither clinically nor radiologically was there any evidence of chronic rheumatic heart disease.

One female patient, in spite of more than five months' continuous treatment with intramuscular and oral hexamethonium bromide, and later with M. & B. 1863, developed what appeared clinically to be the phase of malignant hypertension.

Two out of three chronic nephritic patients whose very high diastolic pressure possibly contributed to their poor renal condition showed some reduction of blood pressure: in one (Case 6) this was associated with deterioration in the renal condition; the other patient was a chronic nephritic with acute exacerbation who was admitted with pulmonary oedema, and whose condition followed the usual course in these cases.

Seven of 14 patients receiving M. & B. 1863 had the same feeling of well-being as those receiving hexamethonium bromide, and this was not related in any way to the fall in blood pressure; in fact, a fall of any significant degree was often associated with a feeling of ill-health.

Five patients showed an unequivocal fall in blood pressure compared with the immediate pre-drug level. One of these died later from severe hypertension while receiving massive doses of the drug; another improved subjectively and objectively on discontinuing the drug, but later died in uraemic coma. In the third case the fall in pressure was associated with marked deterioration of the patient's condition and did not prevent the onset of heart failure a few days later. In the fourth case it was merely the usual result of subsidence of an acute exacerbation of nephritis in a chronic nephritic. The fifth case might represent a genuine therapeutically induced fall in blood pressure, but when followed up in the out-patient department she showed a quick return to her pretreatment level in spite of the continuance of oral therapy.

In several out-patient cases subcutaneous M. & B. 1863, given twice daily, had to be abandoned because of persistent complaints of ill-health and syncope.

We would like again to point out the curious fact that many authorities claim a high incidence of relief of symptoms in hypertension—usually essential or malignant hypertension—with the treatment they propose, without relating this improvement to any fall in blood pressure—for example, the "rice treatment" (empner, 1949; Gounelle, Teulon,

and Chéroux, 1950)—and Sodi-Pallares and Espino-Vela (1951) quote P. B. Camponovo and J. Masello as demonstrating 31% successful results using vitamin K as a hypotensive agent, with 69% of cases claiming subjective improvement without any fall in blood pressure. Chris (1951), in a follow-up of 35 selected patients submitted to sympathectomy, found that, whereas 25% have maintained a fall in blood pressure, some 66% had been relieved of incapacitating symptoms without any relation to the fall in blood pressure.

Using preparations of *Veratrum viride*, Hite (1946) found that 60% of his patients showed a fall in blood pressure; Freis and Stanton (1948) found a fall in blood pressure in 87%, and subjective relief in 79%, and Wilkins, Stanton, and Freis (1949) had similar results. Coe, Best, and Kinsman (1950), however, found the drug unsatisfactory: most of their patients failed to show a fall in blood pressure; and 64% noted subjective improvement on the drug and 60% on a placebo. McNair, Griffith, and Elek (1950), using a higher dose than Freis and Stanton, did not find any significant fall in blood pressure; and Barrow and Sikes (1951), using a purified extract, found that in only 20% was there a fall in blood pressure which might have been significant. Saville (1950), in her communication on pentamethonium bromide, rather dismisses the blood-pressure effects of the drug, but emphasizes its ability to relieve symptoms; and Turner (1950) wondered whether it might not be better to assess the effect of the drug by the patient's symptomatic relief.

It would seem as though any treatment produces a fall in blood pressure in some 20% to 30% of patients and a symptomatic improvement not related to a fall in blood pressure in 50% to 75% of cases.

It has been suggested in correspondence with one of us (S. L.) that the dosage we have used is too large. Paton (1951, personal communication) would put the odds against this causing therapeutic failure as 1,000 to 1, though there is evidence in animals that tetraethyl-ammonium, by promoting the secretion of adrenaline, may swamp its own ganglion-blocking effect. Experimentally, an increase of the dose of hexamethonium increases its ganglion-blocking effect or its duration, or both. Also, the excretion of these drugs in the urine shows that only a small amount is absorbed from the alimentary canal.

We have not emphasized the symptomatic improvement that can occur in many of these cases. We feel that in the present state of our knowledge of hypertension it would be catastrophic to stress the value of a potentially dangerous drug for the treatment of a disease in which symptomatic improvement often occurs with a placebo. We do not feel that we can accept any result as satisfactory without objective evidence of improvement.

It has been suggested that the small quantity of drug absorbed orally may produce a partial ganglion block which relieves the patient without a fall in blood pressure. Sympathetic vasoconstrictor impulses are not the cause of essential hypertension. Inhibition of these impulses is used as a purely non-specific hypotensive mechanism. In a disease in which, so far as we know, the mechanical effect of the hypertension leads to vascular, cerebral, renal, and myocardial changes that are the cause of the symptoms, it is hard to imagine how relief of the symptoms can be produced without any fall in blood pressure or objective evidence of improvement in the patient, unless these symptoms which are relieved are not due primarily to the raised blood pressure. The supposition of partial ganglion block leads to the rather absurd postulation of the disease state of essential hypertension with hypertensive symptoms without rise of blood pressure. In our opinion it is useless to make these assumptions without producing objective evidence of the suggested underlying changes. We feel that, in hypertension, the value of a drug of this kind—namely, one which blocks the ganglia—can be assessed only by its effect on the blood pressure, and, when hypotension is present, by its relief of symptoms.

The difference between our results and those of authors who used the drug only by injection (Smirk, 1950) may be due to the fact that in our previous communication (Locket *et al.*, 1951) and in the present one we have depended mainly upon oral administration of the hexamethonium derivatives. However, our experience with continuous intravenous drip and subcutaneous and intramuscular administration of the methonium compounds does not make us feel any more optimistic about our ability to produce a sustained lower blood pressure unless the injections are given at very frequent intervals and the patients are kept *immobile and erect*. The answer to the different immediate results may lie in the inadequate absorption of the methonium compounds when given by mouth (Milne and Oleesky, 1951).

The different rates of absorption of the drug and the different percentages absorbed when given by different routes form one of the factors accounting for the variability of results. Some of these results are briefly discussed by Wien and Mason (1951). One thing is certain after consideration of these figures—namely, that it is entirely impossible to predict the percentage absorbed or the rate of absorption when the drug is given orally. Even were it possible to predict the response to any given dose "absorbed" by any route and thus to grade the response, it would be impossible

to do this with the oral method. The figures in Tables I-V illustrate this better than words, and make it impossible for one to understand how any clinicians can obtain consistent results when giving the drug by mouth, and how they can claim even to adjust the response by alteration in the oral dose.

Thus Table IV shows that Case "Free" with clinical uraemia excreted only 0.2% of the oral and 8% of the subcutaneous dose, yet Case "Hins," with just as advanced renal disease, excreted 33.8% of the oral and 22% of the subcutaneous dose. Case "Con," with simple hypertension, excreted 24% of 1,400 mg. and only 5% of 3,500 mg. given orally. Case "New" (Table II) excreted 1.4% in 24 hours of a single oral dose of 1,000 mg. and 2.1% of the dose in

TABLE V.—Three Cases Treated with C6 Bitartrate

% excreted in 24 hours	12.3	5.9	11.3

four days, whereas she excreted 44.5% in 24 hours of a single dose of 2,000 mg. given orally and 56.4% in three days. This latter dose was associated with syncope, ileus, and urinary retention. Case "Pop" (Table I) showed a daily excretion of 1.1% to 4.7% of 1,000 mg., but 5.9% of 2,500 mg. and 2.6% of 3,500 mg. given in single doses orally. Subcutaneous administration usually showed excretion figures of 80% in 24 hours, but even these varied from 30% or less to over 80% in the same patient.

When the daily excretion figures exceeded the dose administered, it was because of delay in excreting a dose of drug often given many days earlier. The figures quoted in this paper can be repeated many times from other records.

This failure and delay in absorption might account for the disparity of our results with groups receiving the drug by injection only (Smirk, 1950; Restall and Smirk, 1950), as we have found that the drug is removed from the blood almost as fast as it is injected. It was impossible, with the methods available to us at the time, to estimate blood levels of the methonium compounds, even when blood samples were taken whilst the drug was given by intravenous drip. This failure in intestinal absorption would not account for the difference between our results and those of the series receiving the drug only or mainly by mouth (Campbell and Robertson, 1950; Frankel, 1951).

We have produced an unequivocal maintained fall in blood pressure in one patient treated with oral hexamethonium bromide (and quoted in our earlier communication) and one patient treated with M. & B. 1863, and there were also four doubtful cases with M. & B. 1863—this out of a total of more than 90 patients treated with the drugs, mainly orally, and in spite of the fact that many of our hexamethonium bromide series of patients have now had this drug or M. & B. 1863 for more than a year.

In view of the dangers associated with injection of the drug and the poor and very variable absorption when given by mouth, we consider that further trial of the methonium compounds at present available should be restricted to hospital patients receiving it by injection. Further, that oral use of the drugs is of little value, and, with variable absorption associated with the possible storage of large amounts of the drug in the inert bowel, it might be extremely dangerous in patients not treated in hospital. We have a fair amount of evidence to suggest that oral administration of the drug always causes some degree of intestinal stasis before any reasonable amount of absorption can occur (see Case "New" in Table II). This ileus may be associated with a persistent hypotension because of delayed passage of the drug along the gut and therefore continuance of absorption. There does not appear to be any record of ileus occurring unless the methonium compound is given by mouth, and all recorded fatal cases of this condition were associated with oral administration of the drug.

In conclusion, we ourselves have abandoned the oral use of these compounds in the treatment of any variety of hypertension. We feel that at the moment a regime of rest in bed, sedation, and a salt-free diet is still the safest and most universally applicable method of treatment. However, the continued investigation of the methonium compounds under strict clinical control in hospital centres where there is a full appreciation of the natural variation of hypertension in those diseases in which it occurs is, in our opinion, more than ever necessary in order to obtain a complete picture of the possible restricted field where their administration may be of value.

Summary

M. & B. 1863, an analogue of hexamethonium, was tried orally in several severe cases of hypertension due to essential or malignant hypertension, toxæmia of pregnancy, or chronic nephritis. In none of these cases had there been previously an appreciable fall in blood pressure on rest in bed and ancillary treatment without the hexamethonium derivative.

These detailed results, discussed in the light of more extensive experience, were no more satisfactory than with oral pentamethonium bromide or hexamethonium bromide or bitartrate.

Spontaneous thrombosis of the axillary artery occurred in one patient receiving M. & B. 1863, and another patient apparently developed malignant hypertension while taking it by mouth.

Rest and M. & B. 1863 in combination appeared to produce a fall in blood pressure in five patients: two with chronic nephritis, one of whom is now dead; one in whom the fall in blood pressure was associated with marked general malaise and giddiness followed by congestive heart failure; and two in whom there was, later, a recurrence of symptoms and increase in blood pressure, with death in one case.

In a case of toxæmia of pregnancy associated with essential hypertension, in spite of the proved lability of the blood pressure, intramuscular pentamethonium bromide, oral pentamethonium bromide, and oral M. & B. 1863 failed to produce any improvement or prevent death of the foetus for the fourth time.

Absorption, blood levels, and excretion of the methonium compounds are briefly discussed.

We are grateful to Drs. R. Wien and D. F. J. Mason, of the biological division of May & Baker Ltd., for numerous estimations of the urine content of methonium compounds; to our ward sisters for loyal co-operation in this work; and to Drs. J. Lister, J. Angus, L. G. Collins, R. G. Davies, and A. R. Taylor, without whose help nothing could have been done. We would also like to thank Mr. R. E. Frizzell, our chief pharmacist, for his help and advice, and Messrs. May & Baker Ltd. for the supply of the drug that made this investigation possible. The skilled biochemical assistance of Mr. T. Baker and secretarial assistance of Mrs. E. D. Price have relieved us of many a burden and enabled this work to be completed. Owing to shortage of space more detailed protocols and tables of these 14 cases have had to be omitted, though they are available.

Medical Memorandum

A Case of Schönlein-Henoch (Anaphylactoid) Purpura Treated with A.C.T.H.

The anaphylactoid nature of the syndrome associated with the names of Schönlein and Henoch was first suggested by Osler (1914). It is now generally agreed that sensitization to the haemolytic streptococcus is the basis of the pathology. Histologically the lesion consists of an inflammation involving the terminal arterioles. The presenting symptom in any individual case is determined by the site of the arterioles most severely affected. Gairdner (1948) has pointed out the similarity between the arteriolar lesion in anaphylactoid purpura and the lesion seen in larger vessels in periarteritis nodosa.

A.C.T.H. is of proved value in a variety of allergic states—asthma, drug sensitivities, hay-fever, giant urticaria of unknown origin, contact dermatitis, etc. (Bordley *et al.*, 1949). In periarteritis nodosa improvement has occurred during the administration of A.C.T.H. (Goldman *et al.*, 1950; Stillman, 1950; Shick *et al.*, 1950). The renal lesion in the Schönlein-Henoch syndrome is indistinguishable clinically from that of acute nephritis in which modification of the course of the disease has been reported following the administration of A.C.T.H. (Farnsworth, 1950). There were reasons, therefore, to expect that the hormone might prove of value in anaphylactoid purpura, which has features common both to the allergic states and to periarteritis nodosa.

The following is a report of a case of Schönlein-Henoch syndrome treated with A.C.T.H.

CASE REPORT

A boy aged 3½ was admitted to the Derbyshire Hospital for Sick Children on November 23, 1950. Some five weeks previously he had had a sore throat, with pyrexia and cervical adenitis. Ten days later a purple rash appeared on the thighs and buttocks and he had a persistent severe colicky abdominal pain. Fresh crops of spots occurred prior to his admission, and he had painful swellings of the knees, right hand, and axilla, and painless swellings of the forehead and nose.

On admission his temperature was raised. He had widespread raised purplish macules on the limbs and buttocks and some true purpura. The right wrist was swollen, and at the base of the nose there was a diffuse area of oedema. Tonsils were enlarged but not acutely inflamed. No other abnormal physical signs were seen.

Laboratory Investigations.—Blood count: Hb, 83%; red cells, 3,780,000; white cells, 8,000 (eosinophils 4%, neutrophils 38%, old metamyelocytes 5%, leucocytes 47%, monocytes 6%); platelets, 426,000. Bleeding and clotting times normal; prothrombin time, 19 seconds; E.S.R., 12 mm. in first hour. The urine contained a small amount of albumin, a few granular casts, red cells up to 12, and white cells up to 6 per high-power field of centrifuged deposit. Blood urea, 29 mg. per 100 ml. Stools contained occult blood.

The abdominal pain continued, and fresh crops of the exanthem appeared at intervals of a few days. The stools and urine showed increasing amounts of blood.

Treatment.—A.C.T.H., 5 mg. six-hourly, was started on December 8. On the 19th it was increased to 10 mg. six-hourly, and on the 22nd to 15 mg. six-hourly. Treatment was discontinued on December 27. A total of 640 mg. of the hormone was therefore given over a period of 19 days. During that time the child received a low salt diet and potassium chloride, 0.5 g. daily. Daily blood-pressure readings and eosinophil counts were made. Spot blood-sugar estimations were carried out at the same time daily, and

electrocardiograms were taken twice weekly. The eosinophil count fell from 4% of 8,000 cells to zero in two days, and did not rise again above 1.5% during treatment. The blood pressure, blood sugar, and electrocardiogram remained normal. There was no increase in weight or any personality change.

PROGRESS

Fresh crops of purple macules developed on December 12, 16, and 22. Severe abdominal pain occurred on December 17 and 22, though there were a few days when pain was not present. The albuminuria showed no improvement. On December 12 the Addis count showed: red cells, 99,000,000; white cells, 10,000; granular casts, 2,100,000; hyaline casts, 100,000. On the 18th the Addis count showed: red cells, 324,000,000; white cells, 65,000; granular casts, 4,400,000; hyaline casts, 1,540,000.

After the cessation of treatment the abdominal pain became gradually less severe and the stools were clear of occult blood for the first time on February 10, 1951. Fresh crops of the exanthem continued to occur until he was discharged from hospital on February 12, and he has had further relapses since. Frank haematuria occurred after treatment and since discharge. One relapse on February 28 was associated with an attack of follicular tonsillitis. An intercurrent urinary infection caused by a penicillin- and sulphathiazole-resistant strain of *Bact. coli* cleared on streptomycin.

When last seen in April, 1951, he had no rash, joint swelling, or abdominal pain. The urine contained a large amount of albumin, and the centrifuged deposit showed numerous granular casts, about 100 red cells per high-power field, and moderate numbers of blood casts. The child's general condition was good and he had gained 2½ lb. (1.1 kg.) in weight since discharge.

COMMENT

The course of the illness was typical of that usually seen in a moderately severe case of the Schönlein-Henoch syndrome. There is nothing to suggest that A.C.T.H. modified the course of the disease in any way. During treatment fresh crops of the skin lesion occurred, the abdominal pain persisted, and the urinary findings deteriorated.

While this child was being treated another case in which A.C.T.H. had been used was reported (Stefanini *et al.*, 1950). Their case, that of a boy of 3 years, was comparable with mine, but the dosage employed was smaller. During 14 days of treatment with 5 mg. of A.C.T.H. thrice daily his abdominal pain subsided, but some fresh skin lesions appeared and the red cells persisted in the urine. Further skin lesions and abdominal pain occurred six days after the cessation of treatment. This child was also left with albuminuria, haematuria, and cylinduria five months after treatment. There is little doubt that the failure to respond was not due to a failure of the hormone to stimulate the adrenal cortex, since the eosinophils disappeared from the blood in my case and a personality change occurred in the case reported by Stefanini *et al.*

It is considered that so long as the hormone remains in short supply its further use in this condition is not justified.

Reviews

ANY QUESTIONS?

Any Questions? A Selection of Questions and Answers published in the *British Medical Journal*. (Pp. 240. 7s. 6d.) London: British Medical Association. 1951.

This book, as every reader of the *Journal* knows, has been compiled from the answers given to "Any Questions?" over the last eight years. The difficulties in running a column of this kind are great. The editor must have a panel of experts who are not only knowledgeable but tactful. From reading between the lines it is apparent that a certain proportion of the inquiries relate to the questioners or, even more difficult, to their wives. What treatment would be beneficial in a case of inoperable carcinoma of the stomach? It is no good to answer, None. Moreover, the general body of readers of the *Journal* take a delight in finding the experts at fault and reporting their errors in the correspondence columns. Few of the questions can be answered without a careful check, and access to a large reference library is necessary. Some of the questions are about common knowledge, but at other times extensive research may be required for an answer, particularly to questions in the paramedical fields. However, the problems which most often induce recurrent hunger for information in practising doctors are everyday things which are not well discussed in textbooks and are not included in the standard descriptions of disease, such as sore mouths, cleaning of medicine bottles, sexual disappointments, and morbid human behaviour.

The series has been so successful that repeated demands were received for a selection of the answers to be published. In this first book they have been fairly evenly apportioned over the whole field of medicine, so that there is something to everyone's taste. However, one misses any of the answers to psychiatric problems, which are perhaps the favourite of connoisseurs of "Any Questions?", varying, as they do, so inexplicably from the cold douche to the attitude of *tout pardonner*. It is to be hoped that this will be remedied in the further volumes which are promised. The book does not pretend to be a medical dictionary but rather a breviary for occasional reading. It is not to be read at one sitting, or its abrupt transitions, as from "Dynamite Headache" to "Leopard Injuries," may be confusing. It is small enough and cheap enough to be carried in the pocket and read during those periods of waiting which come to all of us, however busy our days.

L. J. WITTS.

GLUTEAL EVOLUTION

Cold Spring Harbor Symposia on Quantitative Biology. Volume XV. (Pp. 425; 53 figures and 3 plates. \$7.) Cold Spring Harbor, New York: The Biological Laboratory, 1950.

Much of this book is, inevitably, either a summary of known facts or a publication of new ones which may ultimately throw light on the central problem. But one article makes what may be an outstanding contribution to the problem of human evolution. Whether the Australopithecines were our ancestors or not, they make it highly probable that our ancestors started walking, and thus liberated their hands, before their brains reached human size. Washburn points out that in monkeys the gluteus maximus is smaller than the gluteus medius, and that even in the great apes it is an abductor of the thigh. In man, thanks to a shortening and bending back of the ilium, it has become an extensor, and is essential for the erect posture. The view that gluteal evolution preceded cerebral and was a prerequisite of it may be as humiliating to our pride as was Darwin's theory to that of our great-grandparents; but it may be true. Only less revolutionary is the opinion of the systematist Mayr that, if man and his relatives were classified on the same principle as insects, only three species would be recognized, *Homo sapiens*, including modern and Neanderthal man, *H. erectus*,

including *Pithecanthropus* and *Sinanthropus*, and *H. transvaalensis*, including the Australopithecines. At no time, in Mayr's view, was there more than one human species. Schultz's review of the comparative anatomy of man and the apes contains many points which should interest anatomists.

Most of the book deals with human populations and their genetics. Kemp's statistics on congenital diseases in Denmark are the most accurate available for any human community. Neel discusses the fascinating problem of Cooley's anaemia, almost confined to Italians and Greeks, and sickle-cell anaemia, a peculiarity of negroes. Their inheritance is fairly well understood, but we do not understand why natural selection has not eliminated them. If we did we should know a good deal more about congenital disease in general, about human evolution, and about the possibility of negative eugenics.

The British haematological school was well represented by Race and Mourant, the latter of whom bases a racial history of the Mediterranean peoples on their blood groups and types. The longest paper in the book is a still more ambitious attempt by Birdsell to base a history of the Australian natives on their blood characters, measurements, hair colour, and presence of supernumerary molars (in one case a fifth). Posterity will decide whether he has made a real advance in method or raised a pyramid of speculation on a rather narrow basis.

Students of human variation will find data on topics including the numbers of circumvallate papillae, the pattern of the superficial anterior thoracic veins, supernumerary and missing teeth, osteoporosis in ancient Greece, and the variability of the great apes. Classical anthropometry is less stressed than it would have been twenty years ago, and perhaps less than it will be twenty years hence. Several papers, including one by Sheldon, deal with the highly controversial topic of somatotyping.

The standard of printing is very low for the price of the book. But the book does give a wide view of a variety of important problems, and no anatomist or anthropologist will be the worse for dipping into it.

J. B. S. HALDANE.

VARICOSE VEINS

The Treatment of Varicose Veins and their Complications. By Stanley Rivlin. (Pp. 56; illustrated. 10s. 6d.) London: William Heinemann Medical Books. 1951.

This small book is based on the author's essay which was awarded the Hunterian Society's Gold Medal in 1950. In the first half of the book he discusses the anatomy, classification, symptoms, and signs of varicose veins, and in the second half the various aspects of treatment. This has meant a considerable degree of compression in some directions and omission in others, and an over-simplification of many of the problems. The author believes that the "immediate" cause of varicosities is a congenital maldevelopment of the valves at the junctions between the superficial and deep veins of the legs. The clinical examination of all possible types of valvular incompetence is therefore described in great detail, and is very fully illustrated. But factors other than purely developmental ones may be involved. In women veins tend to appear at three periods of life—in adolescence, in the first two or three months of pregnancy, and occasionally at the menopause—all of which are periods of endocrine stress. The hereditary factor in varicose veins is undoubted, but where does it operate?—on the venous valves, on the vein walls, or via the endocrine system? It is possible, by taking too purely a mechanical view, to oversimplify the problems and to narrow the range of treatment. In any case, in practice the presence of much subcutaneous fat only too often makes the interpretation of clinical tests very difficult by masking many varicosities.

The treatment recommended is by means of ligations at sites of venous backflow, retrograde injections, and subsequent injections if required. The author is critical of injection treatment in the presence of venous backflow, but

there are certainly many borderline cases where intensive injection treatment may be very effective if carried out thoroughly, and it may avert operation.

The author discusses ulceration in some detail, but covers eczema and phlebitis in a few lines. It is certain that complicated cases in which ulceration, eczema, and phlebitis are all present call for the greatest resourcefulness and skill, since they will not respond to simple methods. It should be made clear that "elastoplast" types of adhesive dressings should never be used on patients with eczema. The second sentence of the book refers to "Celus"; surely "Celsus" is intended.

REGINALD T. PAYNE.

CORROBORATION IN PSYCHO-ANALYSIS

Essays in Applied Psycho-analysis. Volume II. By Ernest Jones, M.D., F.R.C.P. Essays in Folklore, Anthropology, and Religion. International Psycho-analytical Library No. 41. (Pp. 383. £1 1s.) London: The Hogarth Press. 1951.

This second volume of collected essays in applied psycho-analysis differs from the first in a number of ways. It is concerned exclusively with themes of folklore, anthropology, and religion, a fact which to some extent restricts its general appeal. And, whereas in the first volume the author applied psycho-analytical findings to a variety of cultural fields and problems, in the most important papers in this collection he is more concerned to corroborate psycho-analytical findings by assembling and correlating a vast quantity of anthropological observations. This is not at all surprising when one recalls that his two important essays on the symbolic significance of salt and on the Madonna's Conception through the ear were written between 1912 and 1914—at a time, that is, when psycho-analytical findings about the Oedipus complex provided at the same time a source of profound scepticism and a focus for the most strenuous opposition.

These two essays, together with shorter papers on "The Sexual Ignorance of Savages" and "A Study of the Holy Ghost Concept," are permanent witnesses to Dr. Jones's anthropological acumen and industry as well as to his gifts of exposition. The other essays are in fact mainly expository and to a certain extent propagandist. But the volume as a whole demonstrates convincingly not only that psycho-analytical methods are capable of vitalizing anthropological research, but also that anthropological research is essential to corroborate those psycho-analytical surmises and reconstructions which cannot be supported by direct analysis of case-material.

EDWARD GLOVER.

CLINICAL PATHOLOGY

Panton and Marrack's Clinical Pathology. 6th ed. By H. B. May, M.A., M.D., M.R.C.P., and J. R. Marrack, M.A., M.D. (Pp. 512; 44 illustrations. £1 10s.) London: J. and A. Churchill. 1951.

A book on clinical pathology may be anything from a side-room primer to a vast compendium in which are described in detail every recognized diagnostic test and even such things as the life histories of uncommon helminths. "Panton and Marrack" strikes a happy mean, and in its new and much revised form comprises separate main sections on haematology, chemical pathology, and bacteriology; histology has been eliminated except for a chapter on methods. Outside experts have contributed material on highly specialized subjects; these include fungi and animal parasites. In the section on parasites the use of the term "natural size" in legends to illustrations may mislead: it seems to suggest, for instance, that a hookworm ovum is about the size of a coffee bean.

The later chapters on how to examine specimens and to investigate common clinical states (why no mention of Vincent's infection under "sore throat"?) are perhaps the most useful, since they belong most properly to the subject and are not to be found elsewhere. In view of the book's size and the inclusion of ten colour plates among its many illustrations, the price is reasonable.

SYMPATHECTOMY FOR CEREBRAL
ISCHAEMIA

Many of the earlier experimental studies of the vasomotor control of cerebral blood vessels had negative results, and physiologists were obliged for many years to admit that no certain evidence of the existence of functioning vasomotor nerves could be found. Perhaps the chief reason for this was the confusing passive alteration in size of cerebral vessels which occurred through changes in systemic blood pressure. Anatomists, however, could show that sympathetic fibres supplied the vessels, and they found it difficult to believe that they were functionless. More recent physiological work has shown that these nerve fibres can in fact alter the diameter of cerebral blood vessels. Forbes and Wolff¹ observed the vessels on the brain surface through glass windows in the skulls of experimental animals and found that stimulation of the cervical sympathetic caused constriction and of the vagus dilatation. Other workers have confirmed these findings, and it is now generally agreed that the cerebral vessels are under vasomotor nervous control, though to a lesser degree than the small vessels of the limbs.

Many attempts have been made to help patients with cerebral lesions by operations on the sympathetic nerve supply to the brain. Penfield² has observed cessation of arterial pulsation in the brain during epileptic seizures, and as long ago as 1889 Alexander,³ of Liverpool, performed a sympathectomy for the relief of epilepsy. Further work on epilepsy was disappointing, and White,⁴ after a careful trial, concluded that the operation was without benefit. Vasomotor factors are believed to play a large part in migraine because of the visual cortical effects that occur and because the experimental work of Clark and his colleagues⁵ showed that changes in the dural vessels could cause headache. The route taken by

the nervous factors initiating the vascular changes is still uncertain. They probably do not travel by the cervical sympathetic chain, for White's efforts to treat migraine by procaine block or sympathectomy have been disappointing. He advises, however, that procaine injection of the stellate ganglion should be tried. If it is unsuccessful, ligation of the middle meningeal and temporal arteries combined with partial section of the trigeminal root should be performed in severe cases. Operations for the relief of the fainting attacks and convulsions which occur in some individuals through mechanical stimulation of an abnormally sensitive carotid sinus have met with more definite success than those for epilepsy or migraine. Their aim has been to eliminate the general vasodilator and cardiac depressor impulses which, arising in the carotid sinus, cause cerebral ischaemia through a fall in blood pressure.

Professor Leriche, whose imaginative approach to neurovascular surgery is as fresh and stimulating as ever, writes in this issue of his experience in the treatment of cerebral thrombosis and embolism. He has treated his patients by cervical sympathectomy, stellate ganglion block (which he prefers), and in some cases by carotid periarterial denervation or resection of damaged segments of the carotid artery. He has been guided here, as in his approach to arterial disease elsewhere, by the concept of reflex nervous activity causing spasm of the vessels in the region of a damaged artery. Such a damaged arterial segment should be excised, or, if this is not possible, regional sympathetic denervation carried out. This concept is, as Leriche says, difficult to test experimentally. The beneficial results of sympathectomy can be explained in other ways than by release of spasm. Normal vasomotor tone in the collateral vessels around an area of thrombosis may be lessened, or an increased amount of blood may flow through the collaterals because the more distal vessels become dilated. Edholm and his colleagues⁶ have shown that the resting blood flow in limbs with thrombosed arteries may actually be increased rather than diminished, as would be expected if spasm existed in the collaterals. Pickering,⁷ in a general review of vascular spasm, warns against its too easy acceptance as an explanation of symptoms of disease. He believes that transient cerebral symptoms in hypertensive patients may be better explained by organic obstruction, such as would occur with arteriolar necrosis or thrombosis followed by the rapid development of a collateral circulation. Sympathectomy would be expected to assist such a process by dilating the collateral vessels.

Spasm has often been invoked as an explanation of the shrinking in an arterial trunk seen below the site of lodgment of an embolus and of the ischaemia which results in the limb distal to it. Kinmonth and Simeone⁸ have shown that passive changes in the diameter of large vessels due to variations in blood pressure may cause arterial shrinking that may be mistakenly interpreted as "spasm." Constriction of smaller peripheral vessels due to surgical shock may be similarly misinterpreted.

Whatever the exact nature of the disordered vascular physiology accompanying cerebral vascular accidents, the fact that there is nervous vasomotor control of the cerebral vessels is now established, and sympathectomy may therefore be expected to assist the circulation of blood in them, probably in the same way as it does in the limbs. The physiological basis for periarterial sympathectomy has been questioned in the past, and it is now generally agreed that it is anatomically unsound and without functional effect in the limbs. Improvement reported in the past from the operation can be accounted for by the general vasodilatation which may result from any non-specific operation. The vasomotor nerve distribution to viscera is, however, different from that to the limbs. The sympathetic supply to the hollow abdominal viscera runs with the main arteries and is distributed with their branches, and periarterial sympathectomy is capable in this situation of having a peripheral effect. A similar state exists in the sympathetic nerve supply to the brain, which runs with the carotid and vertebral arteries to be distributed with them to their terminal branches. There is, therefore, a sound anatomical basis for Leriche's attempts to influence brain circulation by section of vertebral nerves and pericarotid sympathectomy.

The results of stellate ganglion blocks for cerebral vascular accidents have also been reported by Mackey and Scott⁹ in Britain and by de Takats¹⁰ and Naffziger¹¹ in the U.S.A. Like Leriche's pioneer work, they are sufficiently favourable to encourage further trial of the technique. If this could be undertaken with objective methods of assessing the changes in vascular and neural function, such as by electroencephalography or estimation of the cerebral blood flow, it would help in judging the clinical improvement brought about by the operation and in studying the underlying physiological changes.

Surgery and physiology owe a debt to Professor Leriche for the way in which he has so often inspired new experiments and the trial of new methods. His article on the cerebral circulation is as stimulating in its thought and vivid in its writing as his many valuable contributions in the past.

PREPARING THE CASE

Some of our correspondents have complained recently about the "delay" in bringing the general practitioners' claim to adjudication. Costs continue to rise, and running their practices becomes an ever more expensive proposition; their plea is therefore understandably for help as soon as possible, and they add to it the fear that their team of negotiators may be unaware of their present needs or lacking in the effort required to meet them. There are several sound reasons which influence the date of the adjudication, and though they were foreseen and have been reported it seems desirable to summarize them here.

The first is that an essential part of the evidence of what remuneration general practitioners actually received from the Government in the year ending March 30, 1950, was made available to the negotiators only last December. As the chairman of the General Medical Services Committee stated at the Annual Conference of Local Medical Committees,¹ it was then known that the Ministry of Health was proposing to use this evidence—though the negotiators do not admit its relevance to the size of the pool—and he added that there were certain implications of it which had to be challenged. It might be thought that these Doctors' Remuneration Tables, as they are called, would be numerical evidence free from any ambiguity. Such is not the case. So diverse and complex are the economics of general practice that minute scrutiny of all evidence of this kind is needed lest unjustified conclusions are drawn from it. The value of this was shown when a similar set of tables, prepared by the Ministry two years ago, was conclusively criticized by the negotiators, and the Ministry had to agree that the figures could not be used. As we pointed out then,² "so ineffectual was the method of inquiry that its results were worthless." To ensure that similar errors shall not now be allowed to vitiate the doctors' case, expert opinion has again been brought in to study the new figures in detail.

The second reason for delay is the need to obtain up-to-date figures of doctors' practice expenses and of the earnings of other professional men. It was only a week ago that the Inland Revenue authorities could make available the results of an inquiry into practice expenses for the financial year 1950-1, and again their interpretation needs close study. The latest figures for earnings in other professions have had to be obtained largely from private sources, since many of them are never published, and professional organizations have been generous in meeting the negotiators' requests.

The main reason now why adjudication is not started to-morrow is that a legal case has to be made out. The profession itself wisely insisted on bringing its case before a judge and on its being presented by counsel. One of our correspondents wrote,¹ "One would prefer rather to present the picture of our invidious position with a few bold strokes without nearly so much detail." That may well be so, but the law demands hard facts and figures, for judges do not come to conclusions until they have had all the available evidence. Had it been possible to reach a broad agreement with the Government by means of negotiation there would have been no need for a detailed presentation of the case. The course of events over the last three years has shown, only too plainly that such an agreement is impossible, and it is for this reason that the profession first asked for arbitration and finally agreed with the Government to accept the present form of adjudication. The result is that the negotiations are far from the procedure common enough in industry when trade union leaders meet employers' representatives to argue about wages. The procedure of adjudication resembles an action at law rather than bargaining round the table, and the course of it is now largely in the hands of legal advisers.

Nor is it merely a question of briefing counsel with some telling figures to show how doctors have been left behind in the struggle to keep abreast of the inflationary wave. Both general practitioners and the Government have agreed that the Spens Report is to be the yardstick of their remuneration. The relation of what doctors are now receiving to what the Report says they should receive, and to what other professional people receive, is evidence that will be contested in detail at every point by the Government side with all its formidable resources. Having this in mind, Dr. Wand emphasized at the Annual Conference that counsel should be given time to study the brief. He referred also to that imponderable feature of the case which is none the less part of it—namely, the status of the profession. To dwell on this without the facts of expenses and receipts would be fruitless, but as a corollary to them it must be presented. Here again full briefing is required, and, as the Conference agreed, "counsel should know all that lay behind the figures which went to make their case . . . all these cannot be learned by any counsel from a paper brief or from one or two interviews."

Especially to those much in need of relief time has dragged slowly. But the importance the Government attaches to the case is shown by the fact that it is to

be represented by the Attorney-General, and a false step now or incomplete briefing on any point would be disastrous. The profession cannot take the risk of hurrying through such heavily mined territory. At every stage the negotiators—all busy men in medical practice—have consulted the profession and have deserved and retained its confidence. The time taken in coming to a conclusion is no grounds for withdrawing it.

DIAGNOSIS OF DEAFNESS IN CHILDREN

A child unable to hear speech from birth may well hear and respond to sounds louder than speech. With its parents it will also attempt, with varying success, to interpret visually what it cannot hear. Thus it is not always easy to appreciate that a young child is unable to hear speech. Until quite recently it was unusual for a child to be suspected of deafness until it was found at the age of 2, or often later, to be backward in learning to speak. Even then the continued dumbness was often attributed to causes other than deafness, for it was not always realized that if a child is unable to hear speech then it will not learn to speak, since speech is ordinarily acquired by hearing and imitating. At one time it was fashionable to talk about "word deafness" and to regard the inability to hear and speak as being due to some disturbance within the central nervous system rather than to a defect in its listening outpost in the ear. This led to many of the children being treated as psychological or psychiatric problems. Fortunately it is now generally appreciated that the site of the lesion responsible for word or speech deafness in children who have never learnt to speak is almost always the internal ear.

The early recognition of deafness in children, its educational management, and the training of special teachers of the deaf all owe much to the pioneer work of Professor and Mrs. Ewing, of the department of education of the deaf at Manchester University. Thanks to them, parents and teachers are more than ever before alive to the possibility and consequences of a child being born deaf, and, as a result, children suspected of being deaf are now brought to the doctor much sooner than formerly—often before they could learn to speak even with normal hearing. But the doctor's task is still difficult: he faces the problem—and it is a very real problem—of finding out if the child really is deaf and, if so, exactly how deaf it is, particularly in terms of speech. Herein lies the crux of the problem—to measure or to estimate the potential hearing for speech in a child who does not know what speech sounds like.

¹ *British Medical Journal Supplement*, November 10, 1951, p. 197.

² *British Medical Journal*, July 8, 1950, p. 93.

³ *British Medical Journal Supplement*, January 26, p. 33.

With most workers in this field the exploration of a young child's sense of hearing is still more of an art than a science, for it entails observation of the child's response, if any, to loud noises, musical sounds, and loud or ordinary speech. By such methods, and with the exercise of great skill and not a little patience, observers with special training can gain an impression of the amount of residual hearing in a young deaf child. It is difficult, however, to express the result of such an examination in a scientific way, as can be done with older children and adults. In them the threshold of hearing for pure tones within the range of speech frequencies is measured with a pure-tone audiometer and the result expressed in chart form on an audiogram. This well-established form of hearing test offers a convenient and accurate picture of the hearing, from which it is possible in many cases of deafness to estimate the hearing for speech. Much of the difficulty in exploring the hearing of young children has been due to the fact that, under the age of 7, a child will not ordinarily give a consistent response to pure tones near its threshold of hearing. Miss M. R. Dix and Mr. C. S. Hallpike¹ in 1947 described their peep-show technique of pure audiometry in which young children were conditioned to respond to pure tones. In this way they were able to plot a pure-tone audiogram for deaf children, often as young as 2. These conditioning tests demand great care on the part of the examiner and, of course, the full co-operation of the child. The latter can best be ensured if the test avoids the use of headphones or other apparatus to be worn by the child, and includes as part of the conditioning procedure a certain degree of pleasurable anticipation. These conditions are provided by the peep-show technique. The child is entirely free to concentrate on hearing the pure-tone sound signal. From previous experience the child knows that only when it hears the sound signal will pressing on a push-button light up the peep-show and enable it to see the pictures.

Dix and Hallpike, in a further paper in this week's *Journal* (p. 235), now give their experiences of this test on 350 children, and they also report on the after-history of many of them in so far as this shows how the educational recommendations based on the audiometric findings have worked out in practice. The procedure of the test has been simplified, and in a single interview of half an hour or less they are able to obtain an accurate picture of the threshold hearing for pure tones within the range of speech frequencies in young children who are hard of hearing and of average intelligence. The resulting audiogram reveals in a graphic and readily appreciable way any poten-

tial hearing for speech. This audiogram, combined with a general assessment of the child's intelligence, enables the observer in a short, single interview to offer advice on the education of the deaf child that has proved to be of great assistance to educational authorities, to whom such children have always been a problem. In cases where it can be clearly demonstrated that there is some residual hearing, the nature of the audiogram may encourage the use of a hearing-aid: this may do much to improve the child's speech and may eventually lead to the child being educated with hearing children. Thus, though it is seldom possible to help young deaf children medically, with the information offered by the peep-show audiometer test it is possible to give constructive advice to parents and education authorities on the possible benefit of a hearing-aid and on the most appropriate form of special education.

ILLEGITIMATE CHILDREN

The position of children to-day is stronger under the law of the land than it has ever been before. But illegitimate children, who represent about 5% of total live births, though sharing in most of the legal and social advances, are still subject to strangely anachronistic disabilities and difficulties. The principal Act is still the Bastardy Laws Amendment Act of 1872,¹ and subsequent amendments have not brought it into line with modern thinking and knowledge. The report² of the Joint Committee of the British Medical Association and the Magistrates' Association on the law relating to the illegitimate child (summarized on page 271) rightly urges that the Government should set up a committee of inquiry to investigate the present law and recommend amendments to it. In the present century there have been only two legal enactments which have substantially helped illegitimate children: the Births and Deaths Registration Act of 1947, which provided for the shortened form of birth certificate, and the Legitimacy Act of 1926, which enabled children born before marriage to become legitimate on the subsequent marriage of their parents. But the proviso in the Act that neither parent should have been married to a third party at the time of the child's birth excludes many children from its benefits. The result, as the report points out, is that the children of fornication, but not the children of adultery, can become legitimate. The only course in these cases is for parents to adopt their own child, a procedure which strikes many of them as strange and unnatural.

The law relating to maintenance is in a muddle, to the detriment of the single mother who tries to keep her child. For the 10% of mothers who successfully apply

¹ *British Medical Journal*, 1947, 2, 719.

to the Courts the maximum award is £1 a week, whereas the children's allowance which can be ordered under the Married Women (Maintenance) Act of 1949 is 30s. Moreover, if the father dies owing payments, no claim can be made against his estate, however wealthy he may have been, for past debts or future maintenance. Under the National Assistance Act the unmarried mother has to maintain her child unless there is a court order against the father. But the number of court orders granted each year is only about one-tenth of the number of illegitimate births. Although the figures cannot be directly related, the proportion probably gives a fair picture of the general situation. Very little is known of how the single mother manages, especially when her child grows older. One interesting study, based on case histories obtained by the National Council for the Unmarried Mother and Her Child, was published not long ago by Dr. Agatha Bowley.³ Local authorities have powers under Section 22 of the National Health Service Act and under Part 111 of the National Assistance Act, but many of them absolve themselves from responsibility by making grants to voluntary organizations to help them carry on schemes which undoubtedly have been helpful in the past but which often have not been considered in relation to to-day's needs.

The social handicaps of illegitimate children are now infinitely less than they were, but lack of means to support the child is still responsible for many unwilling decisions to offer children for adoption. The gap between the infant mortality rates (deaths in the first year of life) of legitimate and illegitimate children continues, though it has narrowed: in 1948 the rates were 33 per thousand live births for legitimate and 45 for illegitimate children, and in 1949 32 and 45 respectively. But, as Lena Jeger⁴ has pointed out, the neonatal figures (deaths in the first month of life) are closer: in 1948 they were 19.3 for legitimate and 27.4 for illegitimate children. This may suggest that the troubles come more from rearing a child single-handed than from prenatal or confinement difficulties. But research on this theme is limited by the fact that separate figures are not published by the Registrar-General after the children reach the age of 1, and the literature is scanty. The publication of the present report should call much-needed attention to the difficulties which may beset unmarried parents and their children. In view of the complications which arise from variations in the laws of different countries, the United Nations might well bring up to date the League of Nations' authoritative report on the subject.⁵

INTRAVENOUS PROCAINE FOR PAIN RELIEF

A study of the use of intravenous procaine for the relief of pain has recently been published in the form of a report to the Council on Pharmacy and Chemistry of the American Medical Association.¹ The report—which is the work of Dr. H. K. Beecher, professor of anaes-

thetics in the Harvard Medical School, and his colleagues—begins by pointing out that "since 1947 almost 50 publications have appeared which report that many varieties of pain, as well as oedema, muscle spasm, itching, symptoms of asthma, and certain eye diseases, have been relieved by intravenous procaine." As these were not controlled trials, the authors have studied the effect of procaine in relieving post-operative pain in 53 patients, comparing the effect of the intravenous infusion of procaine with that of a similar infusion of saline on the one hand and with that of morphine given by intravenous injection on the other. They conclude that procaine certainly has some analgesic action. Saline alone relieved 20% of the patients in the group, while procaine relieved 40%. Morphine, however, relieved 70%. Procaine caused unpleasant symptoms in some patients: thus in one the injection of 75 mg. in four minutes induced generalized clonic convulsions. The commoner symptoms were dizziness, nausea, vomiting, and general numbness. The main conclusion of the report is that intravenous procaine "has no place in the treatment of pain."

It is a little surprising that this report should be necessary, since few doctors would think of giving a continuous intravenous infusion of any drug when several analgesics are available which can be given as a single injection. The report does not deal with the use of procaine for the other conditions mentioned in its first sentence quoted above. Procaine has been shown to have an antihistaminic action,² though a weak one, and therefore it may be beneficial in oedema, in the treatment of itching, and in some forms of bronchospasm. Procaine likewise has an effect on skeletal muscle like quinine and therefore will relieve muscle spasm. However, for any of these conditions intravenous infusion is a very inconvenient and troublesome route of administration.

LIBEL AND SLANDER

Collision with the law of defamation is not an occupational hazard for medical men in the way that it is for authors, publishers, the press, and even for lawyers. None the less, even doctors may fall foul of it, and with more and more reports on patients being called for it is as well that the writers of the reports should know what the law of defamation is. In the past it has been principally criticized on the grounds that it restricts full reporting and honest criticism of matters of public interest, exposes authors and their publishers to unfair risks, and encourages gold-digging actions. The weight that such criticism carries is shown by the fact that Parliament made actions for libel and slander share with actions for breach of promise of marriage the invidious distinction of exclusion from the Legal Aid Scheme. It is as if sufferers from a disease regarded by public opinion as slightly disreputable were excluded from treatment under the National Health Service.

The real problem in reform is to hold a fair balance between the right of the individual that his reputation

¹ *J. Amer. med. Ass.*, 1951, 147, 1761.

² Burn, J. H., *British Medical Journal*, 1950, 2, 691.

³ Defamation (Amendment) Bill. H.M.S.O., London.

shall be protected and the interest of the public that it shall be properly informed. Parliament has not found it a problem easy of solution, and has indeed made no attempt to deal with it by statute since the last century. It took the Porter Committee nine years to publish its report (in 1948), and it was not until Mr. H. Lever, Labour Member for the Cheetham Division of Manchester, got first place in the recent ballot for private Members' Bills that a Bill¹ largely based on the proposals of the Porter Committee has been introduced.

The most profound proposal in the Bill is concerned with what may be called "unintentional libel." As the law now stands, if reasonable people understand a defamatory statement to refer to the man who complains of it, it does not matter that the author or publisher did not intend to defame or even to refer to him. Few would quarrel with this principle, but it can fairly be considered hard that an author who has had the misfortune to create a disagreeable character who can reasonably be identified with X, of whom he has never heard, should be liable to be mulcted in heavy damages in circumstances in which no blame can be ascribed to him, and in which the cause of the damage to X's reputation is really an unhappy coincidence. The present Bill proposes that in this situation the defendant shall be immune from liability in damages so long as he publishes a correction and apology.

The Bill further deals with the defence of "justification." It has always been a complete answer to an action for defamation that the words complained of are "true in substance and in fact"—rightly so, for it is not the function of the law to protect a reputation which is not deserved. But the defence has been an onerous one to establish, because it is necessary to prove that all that has been complained of is substantially true. If it is written of John Smith that he is a thief and a swindler, the writer's defence will fail if he proves that Smith has been convicted of obtaining money by false pretences but does not prove that he has been convicted of larceny. The proposal to cure this is that, if the words complained of make more than one distinct charge, the defence of justification will succeed if it proves so substantial a part of the charges that those not proved do not add materially to the injury to the plaintiff's reputation: that is, the writer need only prove John Smith's conviction for false pretences provided the jury thinks that a swindler is as bad as a thief.

The Bill proposes to extend and clarify the situation in which newspapers can plead the defence that what they have published is a fair and accurate report of proceedings before the Courts and in other public and "quasi-public" bodies. There is also a proposal to cure some of the anomalies which have arisen from the manifold efforts of the Common Law of England—which in theory existed complete from the times of the Angevin kings and is declared only through the mouths of His Majesty's judges in whose bosoms it resides—to cope with the problems posed by the Electronic Age. Sound broadcasts and television are to be treated as libel, not slander, whether they are made impromptu or from a written script.

RIFT VALLEY FEVER IN SOUTH AFRICA

The news, reported by Mundel and Gear,¹ that Rift Valley fever has broken out in South Africa raises many interesting questions both for the medical man and the veterinarian. Rift Valley fever was first described in 1931 by Daubney, Hudson, and Garnham² when an outbreak on the shores of Lake Naivasha in the Rift Valley in Kenya attacked sheep, cattle, and man. The infection was found to be due to a virus. Some years previously, in 1912, Montgomery³ had described from the same area an outbreak of a disease attacking sheep and causing necrosis of the liver: at that time it was not recognized that a virus was the cause.

A mouse protection test carried out on sera from various parts of Africa gave evidence in a survey in 1936 that the virus had almost certainly infected persons living in the Southern Sudan, Uganda, and French Equatorial Africa but not in West Africa.⁴ The virus of Rift Valley fever was later duly isolated in Uganda from wild mosquitoes captured in a forest area, but no epizootic or epidemic has ever been known to occur in that country.⁵ Now in recent months an epizootic has occurred in South Africa. The first evidence of the disease was obtained from a farm near the Palmietfontein Airport just outside Johannesburg, where a bull died with necrosis of the liver. A virus producing the same lesions in mice as Rift Valley fever was isolated from the tissues of the bull at necropsy and from the blood of three veterinary surgeons and two attendants who suffered from illness after the necropsy.

It was at first considered likely that the infection had been introduced by air, as the airport receives traffic daily from Central Africa, including Kenya. Doubt was thrown on this suggestion when it was found that a widespread epizootic involving sheep and lambs had occurred in the Orange Free State and the Western Transvaal, preceding the death of the Johannesburg bull. Although there is no record of Rift Valley fever ever before having occurred in South Africa, it should be possible to settle the question definitely, for Findlay and Howard⁶ have recently shown that immune bodies remain for at least 20 years in the blood of those once infected. The question also arises, What happens to the virus of the fever when it is not, at rare intervals of approximately 20 years, causing epizootics in Africa? A possible clue, which requires following up in larger animals, is the fact that in mice the virus is adsorbed by the larval form of a tapeworm which is normally parasitic in the liver.

We record with regret the death in Colombo on January 23 of Sir Frank Gunsekera, who besides being a well-known general practitioner was also the Deputy President of the Ceylon Senate.

REFRESHER COURSE FOR GENERAL PRACTITIONERS

THE PROS AND CONS OF IMMUNIZATION—II

BY

ROBERT CRUICKSHANK, M.D., F.R.C.P., D.P.H.

Professor of Bacteriology, St. Mary's Hospital Medical School, London, W.2

In the previous article I discussed the principles of artificial immunization, and, despite the attendant risks, it was thought that, whenever immunization was safe, practicable, and effective, prevention was preferable to cure. In this paper the procedures and indications for inducing active or passive immunity in individual infections are discussed.

Diphtheria

Protection against diphtheria may be produced by passive or active immunization or by a combination of the two methods. Passive immunization used to be practised frequently when a case of diphtheria occurred in a family and it was necessary to protect the other susceptible children as quickly as possible. Nowadays, when most children are actively immunized in infancy, passive protection is rarely needed. When the need does occur in a family or residential nursery or school, all contact children are given an intramuscular injection of 500 units of refined diphtheria antitoxin contained in 0.5 ml. or less, while active immunization of children up to the age of 7 years is begun immediately, or after two weeks when the temporary protection from the antitoxin has been largely lost. Any contact children over 7-8 years who have not been immunized within the past two years should be Schick tested 12 hours or so before receiving the antitoxin. If they are Schick-positive and give a history of previous immunization they should be given one dose of a suitable prophylactic, or two doses at a month's interval if there is no such history. If a child gives a pseudo-positive response (an erythematous reaction with the control material as well as with the Schick toxin) he should not be injected with any diphtheria prophylactic, as he may react severely to it; instead, he should be retested after three to six months.

Active immunization is best carried out in infancy, preferably around 6 months of age, when antibody derived from the mother will have disappeared and the child is less likely to suffer from psychological trauma as some older children do when given repeated injections. Probably the best diphtheria prophylactic for use in this country is P.T.A.P. (purified toxoid aluminium phosphate precipitated), which has a uniformly good antigenic potency and produces the minimum of local reaction. It is not yet, however, generally available as a free issue, whereas A.P.T. (alum-precipitated toxoid), another very good prophylactic, is. Two doses of these prophylactics should be given into the deep subcutaneous tissue in amounts of 0.3 ml. of A.P.T. or 0.5 ml. of P.T.A.P., with an interval of not less than four weeks between the two injections. This interval may be extended to six months or more. The resulting immunity lasts for two to four years in most children, and if this primary immunizing course has been given in the first year of life a further injection should be given about the age of 5 years, when the child goes to school, or earlier if convenient. For this booster dose one of the less powerful prophylactics

like T.A.F. (toxoid-antitoxin floccules), 0.5 ml., may be used. Some authorities recommend a second booster dose towards the end of school life, but this is not essential unless the individual is likely to be going to a country where diphtheria is still uncontrolled.

It is most desirable that a high proportion, around 70-80%, of pre-school- and school-children be protected against diphtheria if this infection is to be effectively controlled. Many parents know the disease only by name and may require a good deal of persuasion to have their children immunized against what is to them a rather hypothetical danger. The family doctor must therefore be prepared with good reasons to persuade the doubters of the value and safety of immunization against diphtheria. Even so, we must admit that certain of the more invasive strains of *Corynebacterium diphtheriae*—for example, the gravis and intermedius types—may break through some degree of antitoxic immunity. It is therefore advisable that throat swabs should be taken for bacteriological examination from any patients with exudative tonsillitis or pharyngitis.

Smallpox

Smallpox in its typically virulent form has not occurred as an epidemic disease in this country for many years, although a modified form called alastrim was prevalent in the years between the two great wars. However, localized outbreaks of smallpox occur from time to time and often cause great alarm and much administrative anxiety and expense before the public can be assured that the danger is past. The main worries about such sporadic outbreaks are that the primary case, arriving perhaps by air from the Middle or Far East, may be so mild and atypical as to be missed, that the disease can be highly infectious in the early stages, and that only a small proportion of our population have any degree of immunity against the infection. The tragic deaths from smallpox in recent years of student nurses and others who had never been vaccinated, the upheavals in communities where outbreaks have occurred, and the risks of primary vaccination during school or adult life are part of the arguments that may be used to convince parents of the advisability of having children vaccinated in the first year of life, when severe reactions or complications are very rare.

Vaccine lymph may be obtained from the nearest public health laboratory by sending the appropriate request form, or, if there is urgency, by telephonic request. The potency of the lymph deteriorates quickly if it is kept at room temperature, and therefore the vaccination should be done as soon as possible after the lymph has been received; failing this, the lymph should be stored in a refrigerator and used within two weeks. Primary vaccination may be done at 3-6 months of age, either by scarification or by the multiple pressure technique. In the former method the skin is cleaned with soap or ether and a single linear scratch $\frac{1}{4}$ in. (0.6 cm.) long is

made on the epidermis with a Hagedorn needle or other suitable instrument through a drop of lymph. In the multiple pressure method the lymph is first spread over an area of about $\frac{1}{4}$ in. (0.3 cm.) square, and with a large flat-sided needle a series of some 20-30 pressures are made on the skin through the lymph (for details, see *Any Questions?** 1951, p. 139). The upper arm or in girls the ankle area are the sites of choice; the thigh should not be used.

Opinions vary about the advisability of covering the vaccination immediately with a dressing; the important point is that the lymph should be allowed to dry before the vaccination site is covered in any way. A dressing may be applied after four to five days, when the vesicles begin to appear, and in the later stages the lesion may be dusted with an antiseptic powder. In older children or adults, in whom the reaction may be more severe, the arm should be rested in a sling. If there is no response the vaccination should be repeated after a week, and it may be repeated a second time if there is still no reaction. Natural immunity in a child of 3-6 months is very rare.

In those who have been vaccinated before, one or other of two reactions different from typical vaccinia may occur. In the "accelerated reaction" vesicles appear early (within two to three days), and the lesion reaches its maximum intensity in four to five days, indicative of some degree of immunity. In the "immune reaction"† a raised itchy reddened lesion, without vesiculation, appears within one to two days, and fades quickly; this reaction, regarded as an allergic phenomenon, may or may not indicate a good degree of immunity. If in doubt the vaccination should be repeated a week later with fresh lymph.

Primary vaccination gives immunity to smallpox for a period of seven to ten years, and ideally every person should be vaccinated in the first year of life and again about the tenth year of life. It is essential that any individual who may run the risk of intimate exposure, such as hospital staff and emigrants to certain countries, should be vaccinated or revaccinated before they are exposed to this risk.

Whooping-cough

Whooping-cough, or pertussis, comes next to measles in its high incidence in the child community. About 40-50% of children have been attacked by the age of 5 years, and about 70% by the age of 10-12. The infection, caused by *Haemophilus pertussis*, is most severe in infancy. Nearly half the deaths occur in the first six months and about two-thirds within the first year of life, but whooping-cough may be serious in any child up to 3 years of age, causing a protracted debilitating infection with the risk of secondary lung complications. If prophylactic vaccination is to be used, therefore, it should be given to children as early as possible, and preferably within the first six months of life. With an effective antigen the antibody response is apparently as good in infants aged 3-6 months as in older infants. Recent experience in America and the results of controlled vaccine trials in this country indicate that a considerable degree of protection can be given to young children by two or three injections of pertussis vaccine.

*Obtainable from the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, price 7s. 6d. (postage 6d.)

†It is suggested that this term be discarded and replaced by "maximum local reaction (non-vesicular) on second/third day."

There may, however, be considerable variation in the protective value of different vaccines, and unfortunately there is as yet no generally accepted animal test by which pertussis vaccines can be assayed. Pharmaceutical firms preparing pertussis vaccine are now well aware of the requirements for the production of good vaccines, and if a doctor is in doubt about the particular brand of vaccine to use he may be able to obtain advice from his medical officer of health. British vaccines are usually prepared in strengths of 10,000 to 20,000 million organisms per ml., and it is customary to give three deep subcutaneous injections of 0.5 ml. at intervals of three to four weeks. Immunization should be begun, if possible, about the second or third month of life, and at present should probably not be offered to children over 3-4 years unless there are special indications. Injections of pertussis vaccine should not be given to a child with a history of convulsions or within three weeks after vaccination. With effective vaccines immunity lasts for at least two years, and a booster dose need only be given if there are special indications for it—for example, a child aged 3 vaccinated in infancy and intimately exposed to the risk of infection.

Combined Diphtheria and Whooping-cough Immunization

It would be an obvious advantage to combine diphtheria and pertussis immunization so as to reduce the number of injections to be given to the infant. Diphtheria toxoid and pertussis vaccine have been combined as one prophylactic and the evidence indicates that the specific antibody response to each of these prophylactics is not thereby impaired. If the pertussis vaccine is known to give good protection the combined prophylactic may be given in three doses, beginning about the sixth month of life. If, however, there is doubt about the protective value of the pertussis vaccine it is wiser not to give combined immunization, since failure of the pertussis vaccine may antagonize parents against immunization in general. There is the further risk of post-inoculation poliomyelitis, which is particularly associated in this country with injections of combined diphtheria and pertussis prophylactic.

Measles

As the virus of measles has not so far been cultivated artificially, there is no method of producing active immunity to this infection by injection of a virus vaccine. Human serum containing antibody to the measles virus may, however, be used either to give complete protection or to modify the attack in a child who has been exposed to the risk of infection. Serum from a convalescent case would be most suitable but is difficult to obtain, since measles is not often seen in young adults who might be asked to donate blood for this purpose. Adult serum, prepared from small pools of donors to reduce the risk of homologous serum jaundice, has been mostly used, but cannot be guaranteed to give complete protection unless injected in very large doses. However, if adult serum is fractionated so as to obtain the antibody-containing globulin (gamma-globulin) in concentrated form, attenuation or complete protection may be obtained with doses of 1-3 ml.

Gamma-globulin is not generally available in this country and the practitioner will usually have to aim at producing a modified attack by giving to the exposed child 10 ml. of adult serum, obtainable from the nearest public health laboratory, as early as possible after

exposure. When it is remembered that the rash in measles does not appear until the fourth day of the disease, a child who has been in contact with an unsuspected case during the previous two to three days may already be incubating the infection for four to five days before any serum can be given. Attenuation can only be expected if serum is given before the sixth or seventh day of incubation, counting the rash as the fourth day. Modified measles, characterized usually by a discrete or sparse rash without catarrhal symptoms, minimizes the risk of complications, and will give the affected child considerable, but perhaps not complete, protection against subsequent attack.

Whole citrated blood from one of the parents is sometimes used. The blood (10–15 ml.) is drawn into a syringe containing 1–2 ml. of 2.5% sodium citrate, and is immediately injected intramuscularly into the child. Apart from the large amount of blood, which causes an unsightly haematoma, there may be some risk in this procedure of producing rhesus sensitization unless rhesus typing can be done beforehand.

Rubella, Mumps, and Poliomyelitis

Practitioners often ask about the possibility of protecting contacts against these infections by the use of convalescent serum or gamma-globulin. In the case of rubella a woman in the first two to three months of pregnancy who is exposed to attack may, if she develops the infection, give birth to a child with serious congenital defects such as deafness or blindness. The only protective measure that has so far proved effective is the injection of a large dose of gamma-globulin prepared from the serum of convalescent cases of rubella; such material is not likely to be available. Similarly, gamma-globulin prepared from mumps convalescent serum has given some protection against secondary orchitis in young male adults. Convalescent serum gives no protection against poliomyelitis or against paralysis in a case in the pre-paralytic stage.

Tuberculosis

The possibility of using a vaccine of tubercle bacilli to give some protection against tuberculosis to susceptible members of a family or a community exposed to the risk of infection has in recent years become a practical proposition. Killed vaccines were found to be ineffective, but the use of a living attenuated and practically non-virulent bovine strain, called B.C.G. (Calmette-Guérin bacillus) after the French originators, has now become accepted in many countries as a method of protection against tuberculosis. The vaccine may be given, by intradermal injection or scarification, to infants born into a tuberculous family, to susceptible adolescents about the time they leave school, and to medical students and student nurses who may be unduly exposed to the risk of infection.

In the older groups a tuberculin test should first be done to find out whether or not the individual has already latently acquired an infection, and only if the test is negative should B.C.G. vaccine be given. As it is a culture of living organisms the vaccine must be used within 10 days or so of its preparation, and the inoculated individual should be tuberculin tested six to eight weeks after vaccination to find if he or she has now become tuberculin-positive. The positive reactor has ordinarily a greater resistance to tuberculous infection than has the negative reactor. B.C.G. vaccine is at present distributed on request to hospitals and chest clinics where there are specialists in tuberculosis. Any

doctor who wishes to use the vaccine should get in touch with the nearest centre where a specialist is likely to be available, or he may apply directly to the Ministry of Health on Form B.C.G. 1.

Enteric Fever

Vaccination against the typhoid-paratyphoid group of fevers is not ordinarily recommended in civilian practice except for nurses going to fever hospitals and for those going abroad to countries where the infection is still prevalent. The vaccine consists of killed cultures of typhoid, paratyphoid A, and paratyphoid B bacilli in the proportion of 1,000 million, 500 million, and 500 million organisms per ml. respectively, and is given in two subcutaneous doses of 0.5 ml. and 1 ml. at an interval of seven to ten days. If the vaccine is "alcohol-treated" to preserve the Vi (or virulence) antigen of Felix the doses should be 0.25 ml. and 0.5 ml. Children under 1 year of age do not need to be vaccinated; the dose for children aged 1–5 years should be about one-third of the adult dose, and for children aged 5–15 years one-half. Immunity, which is by no means absolute, may be expected to last for about two years. Booster doses are given yearly to those likely to be exposed to the risk of infection.

Local or constitutional reactions may occur after an injection of T.A.B. vaccine, which should be given late in the afternoon and the patient advised to go early to bed, taking 5–10 gr. (0.32–0.65 g.) of aspirin if need be.

Scarlet Fever

Scarlet fever is to-day a mild infection distinguishable from streptococcal tonsillitis only by the presence of an erythematous rash. The rash is caused by an exotoxin produced by certain strains of *Streptococcus pyogenes*, and this toxin (which cannot be satisfactorily converted to toxoid) has been used to immunize susceptible individuals against scarlet fever. Because four to six injections of increasing doses of toxin are needed, because local and systemic reactions are not infrequent, and because scarlet fever is so mild and readily amenable to antibiotic therapy, active immunization against this infection is not practised nowadays except perhaps for administrative reasons—for example, among nursing staff in a fever hospital. Passive protection of intimate contacts in a family or institution by an injection of the refined scarlatinal antitoxin has also been mostly discarded.

Influenza and the Common Cold

Epidemics of influenza are caused by viruses which can be cultivated artificially on the chick embryo; there are two main types, called A and B. Vaccines of these two types, given in one injection shortly before exposure, have given a considerable degree of protection against the homologous virus infection. The obstacles to the large-scale use of influenza virus vaccine are the uncertainty of foretelling an epidemic of influenza; the difficulty, when an epidemic occurs, of identifying the infecting strain in time to prepare sufficient vaccine; and the apparently short duration of the artificially induced immunity. Efforts are being made to overcome some of these difficulties, and suitable vaccines may become available, particularly for the protection of those in important posts—for example, nursing staff and medical men—at the onset of an epidemic. As outbreaks usually occur in the early spring, the best time to give the prophylactic vaccine is in November or December.

The common cold is also believed to be due to a virus which, unlike the influenza virus, cannot be cultivated artificially. Therefore at present there is no hope of a common cold virus vaccine. Some individuals, however, seem to suffer unduly from secondary bacterial infections—sinusitis, bronchitis, and the like—after an attack of the common cold, and for these subjects mixed stock or autogenous bacterial vaccines have been recommended in the form of a prophylactic course of injections in the late autumn.

Yellow Fever and Cholera

Vaccination against these tropical infections is required only for travellers to or through certain countries where these diseases are endemic. Inoculations with the living yellow fever virus vaccine are given at certain specified centres named in the list set out in the "Notes to Travellers" issued at the Passport Office and the travel agencies. Certificates of inoculation against smallpox, typhoid, yellow fever, and cholera must be on the prescribed International Form, which the traveller again should obtain from a travel agency or the consulate of the country to which he is going. If his own doctor is unwilling to undertake vaccination or inoculations against typhoid and cholera, the traveller may be directed to one of the centres where these inoculations are being done regularly—for example, in the London area there are inoculation clinics at the Tropical Diseases Hospital, at the Wright-Fleming Institute, St. Mary's Hospital, and at the B.O.A.C. Airways Terminal. In the provinces the doctor can usually find out from the medical officer of health where facilities of this kind are available.

Inoculations against plague and typhus fever are not at present required for travellers abroad.

THE LAW IN RELATION TO THE ILLEGITIMATE CHILD

On February 1 a joint committee* of the British Medical Association and the Magistrates' Association, under the chairmanship of Dr. DORIS ODLUM, issued a report† on the present law governing the custody and maintenance of the illegitimate child. The report has received the unanimous approval of the Council of the British Medical Association, but the Council of the Magistrates' Association, in agreeing to publication, wishes to make it clear that it is not necessarily committed to all the views expressed therein.

After reviewing the legal and historical background of the existing law on bastardy, the committee discusses the rules governing the application to a court for a maintenance order, the limitation of the hearing of such cases to magistrates' courts where the maximum order that can be made is £1 a week, the statutory demand for corroboration of the mother's story, the place of blood tests, the registration of "voluntary agreements," guardianship, adoption, and legitimation, as well as the psychological aspects of illegitimacy and the dangers of poverty in these cases. The committee's recommendations are summarized below.

*The members of the joint committee were:—For the British Medical Association: Dr. Doris Odlum (chairman), Dr. F. Bodman, Dr. Denis Carroll, Dr. T. P. Rees, and Dr. J. G. Thwaites. For the Magistrates' Association: Mrs. E. G. F. Birley, Major Reginald Bullin, Mr. B. L. O. Henriques, Dr. W. S. Macdonald, and the Rt. Hon. Lord Merthyr. Co-opted: Dr. H. Mannheim, Dr. J. C. W. Methven, and Mr. Claud Mullins.

†The report is obtainable from the Finance and Business Officer, British Medical Association. The price, including postage, is sixpence.

Recommendations

1. The law concerning the maintenance, custody, and welfare of illegitimate children is in urgent need of revision.
2. A committee of inquiry should be set up by the Government to investigate the present law relating to the maintenance, custody, and welfare of illegitimate children with a view to recommending amendments to the law.
3. Under certain conditions a married woman should be enabled to apply for maintenance in respect of an illegitimate child.
4. The High Court should be given concurrent jurisdiction to hear claims for the maintenance and custody of an illegitimate child.
5. When a magistrates' court hears a bastardy case magistrates of each sex should be members of the court.
6. The legal necessity for the corroboration of the applicant's story should be modified.
7. The ruling in the case of *Johnson v. Pritchard* should be modified so that, subject to challenge, all letters between the parties would be admissible in evidence.
8. The maximum amount that can be ordered by a magistrates' court for the maintenance of an illegitimate child should be increased to that applicable in the case of children born in wedlock.
9. Courts should be enabled to extend the duration of bastardy orders beyond the age of 16 in cases where a child is continuing a course of education or training beyond the age of 16.
10. The words "putative father" should not be used in bastardy orders and simple words with the same meaning should be substituted therefor.
11. The usefulness of blood tests and the procedure concerning the use in paternity cases should be further investigated.
12. Further investigation is desirable into the procedure to be adopted by the courts when a defendant alleges that the mother of an illegitimate child has been promiscuous.
13. It should be possible for a voluntary agreement to maintain an illegitimate child to be registered with a court and thereafter to be enforced or modified as if it were an order of a court.
14. In exceptional cases a court should be able to grant an application made by the father for the custody of an illegitimate child.
15. There should be a provision in the law declaring that Section 4 (2) (a) of the Guardianship of Infants Act, 1925, as amended by the Children Act, 1948, is applicable to illegitimate children.
16. There should be further investigation into the necessity for the provision in the Legitimation Act which precludes the legitimation of a child in a case where one of the parents was married to a third party when the child was born.
17. The present law, whereby proceedings to enforce payment on a bastardy order cannot be taken after the death of the father, should be amended.
18. Marriage should not be regarded as necessarily desirable when the birth of an illegitimate child is probable.
19. Provided there are no good reasons to the contrary, an illegitimate child should remain with the mother.
20. As far as possible, every illegitimate child should be brought up in a home and a family.
21. The emotional needs of children must be considered when arrangements are being made for the adoption of an illegitimate child, or when foster-parents are being chosen.
22. The fact of a child's illegitimacy should either be explained at an age prior to adolescence, when the child can understand the implication, or earlier in response to questions from the child. The child should not be told of its illegitimate birth during adolescence unless the case has first been referred for expert advice.
23. A new name for the illegitimate child is desirable.

Nova et Vetera

THE NOTTINGHAM GENERAL HOSPITAL

A History of the General Hospital near Nottingham. By Frank H. Jacob, M.D., F.R.C.P. (Pp. 353; 52 plates. £1 5s.) Bristol: John Wright and Sons. 1951.

In July, 1948, most of the former voluntary hospitals in this country came under State control. Since that date there have appeared several histories of individual hospitals under the old regime—obituaries which, while recognizing the inevitability of change, to a certain extent breathe the spirit of the "dear departed." Dr. F. H. Jacob, who himself served the hospital so faithfully for so long, has written much more than a history of the Nottingham General Hospital, for he has striven successfully "to tell something of the lives of the more notable of the vast throng of people who devoted such loving care" to the hospital's welfare. He has done more than this. He has thrown his own personality into the book by inserting a numerous series of comments, relevant and irrelevant, humorous and serious, which delight and surprise though they occasionally tantalize the reader.

The style of the book is leisurely, and there are many quaint allusions which almost remind one of Robert Burton. Here is the start of Chapter 17: "In Elizabethan days the physician, Dr. Gilbert, gave to science the foundation of electricity. In 1895, Röntgen, aged 50, returned the debt of [sic] giving x rays to the aid of medicine. 'Chance favours only the mind that is prepared.'—Pasteur." The reader will be interested to note that the new x-ray department was placed under the charge of the honorary dentist, and that the first photograph of a stone in the kidney was taken in 1900 with an exposure of 20 minutes.

The author's firm opinion is everywhere expressed. In speaking of the laboratory, he asks the question, "Should a big hospital include scientific research in the work of its laboratory? Yes! It is a positive duty!" The account of the early days of the hospital throws a flood of light upon the life of those times. The wards were opened in 1782, and as early as 1785 were begun the annual feasts to celebrate the hospital's anniversary of its birth. In that year "a sumptuous entertainment was provided," and the company had to drink over a dozen toasts to various people and bodies. The menu for the feast of 1814 is given, and includes two kinds of soup, three varieties of fish, 18 different dishes of meat and game, and eleven sweets. The author comments: "It is almost unnecessary to add that the afternoon was spent in a very cheerful manner."

There are pen pictures of many famous doctors and laymen, among whom one may mention Francis Sibson, W. H. Ransom, W. B. Ransom, Lord Trent, and Sir Charles Seely. One anecdote of Lord Trent remains fixed in one's mind: the old man was crippled and had to be carried everywhere, his limbs were all bent and fixed, he could not move his neck, but he was intelligent and would talk with great rapidity and conduct his business efficiently. If any visitor sympathized with him he gave orders that "that person must never come here again, you know, when they are sorry for me I begin to be sorry for myself."

There is a good account of Sibson's work at Nottingham which contains many new facts about that famous physician's early days. We noted here the only inaccuracy which we found in the book—Sibson was appointed to the staff of St. Mary's Hospital in 1851, not 1861. It is noteworthy that the author has drawn on the obituaries in the *British Medical Journal* for at least 12 of his miniature biographies.

There are many curious facts in this book. We learn that in the early days of the hospital each inmate, whether patient or staff, was allowed 2½ pints of beer each day, and that the hospital brewed its own beer. In those days there were no resident night-nurses, but "watchers" were brought in from outside to keep watch during the night

and were paid 6d. each night. But the best of the old customs which will undoubtedly appeal to many moderns, whether medical or lay, is the respect which was shown to the house-visitors. The regulation for 1783 runs as follows: "The Hospital is to be visited by the House-Visitors once every day for the week, after their appointment, when they are to walk through the wards with white wands, that they may be known to be House-Visitors; and at noon as they enter the wards, the nurses are to withdraw, and the patients to stand by the sides of their respective beds."

Yes, those were the days!

V. ZACHARY COPE.

Correspondence

Because of the present high cost of producing the Journal, and the great pressure on our space, correspondents are asked to keep their letters short.

Paying for the Health Service

SIR,—The most common of all misunderstandings about the National Health Service is the belief that it is paid for by the Insurance Fund. While this persists it will be difficult to persuade many thousands of patients to be economical in their use of the Service.

It is saddening to find this fallacy repeated in an article in your issue of January 19 (p. 129) from a medical statistician. She actually refers to "National Health stamps." There have been none since 1948. When I last had occasion to give the figures they showed that out of £486m. spent in a year on the National Health Service only £40m. came as grant from the Insurance Fund, and of course the whole of the well-known £400m. (the "ceiling") from general taxation.—I am, etc.,

House of Commons, S.W.1.

HILARY A. MARQUAND.

Ovarian Dysmenorrhoea

SIR,—I find it difficult to resist criticizing the article by the late Mr. D. C. Wiseman and Mr. W. M. Thomas on the surgical treatment of ovarian dysmenorrhoea (January 19, p. 141). We have only imperfect knowledge of the cause of menstrual pain, but we presume that pain felt before the period is due either to an abnormal blood congestion of the whole pelvic organs or to a normal congestion in a sensitive woman. Their criterion of diagnosis is pain caused by compression of the ovaries during bimanual examination which "accurately" reproduces their peculiar type of dysmenorrhoea.

Most women suffer painful sensation if their ovaries are squeezed enough, but what woman can identify "accurately" the nature of the pain? The same pain can be produced in these patients if the uterus also is compressed. How much discomfort is caused depends on the time in the cycle at which the examination is made. If just before menstruation, most women will feel discomfort, which will be absent just after the period. But the authors do not state at what phase their patients were examined.

In assessing the "cure" rate (only 49%) patients are included as soon as six weeks and up to three years. What was the percentage of "cures" during the third year? To estimate a "cure" six weeks after the operation is ludicrous, for whatever treatment is given will render the first period painless. The assessment is based solely on the disappearance of a subjective symptom which cannot be measured.

In any case, the majority of the 54 patients (77%) below the age of 30 might be expected to lose their pain after 30 with no treatment at all. There is no mention of whether these 70 women had received other simpler and more orthodox treatment before submitting to an operation which seriously interferes with the ovarian blood supply, inasmuch as the ovarian arteries are divided.

The removal of 27% of normal appendices is irrelevant, because if the appendix has no disease it cannot easily contribute to pre-menstrual pain. Incidentally, quite a number of young

BENGER LABORATORIES LIMITED · HOLMES CHAPEL · CHESHIRE · ENGLAND

women date their dysmenorrhoea from appendectomy or a pelvic operation. For example, a young woman from whom I dissected a large dermoid ovarian cyst two years ago has had intractable dysmenorrhoea ever since.

Cotte's pelvic sympathectomy has a rightful place in the treatment of certain cases of severe dysmenorrhoea when other treatment has repeatedly failed, but by this operation there is no interference with the pelvic blood supply.

I can also understand that removal of large dilated veins from a pampiniform varicocele may relieve congestive pre-menstrual pain, but why divide the ovarian arteries when pelvic sympathectomy would be a surer way of denervation?

Some of us believe that interference with the main blood supply of the ovaries causes serious ovarian disability. I notice that only 16% of the married women became pregnant after the operation. It would be useful to know the previous parity of those who conceived.

The authors also recommend a division of the infundibulo-pelvic ligament, with all that it contains, if an operation for removal of the appendix finds that it "does not show definite signs of acute inflammation." Dysmenorrhoea is a subjective symptom which is usually inherent in the woman's background, personality, and her early training. This is especially true of pre-menstrual pain.

Almost any treatment is successful for a short time, and occasionally permanently. I suggest that if these 70 women had had nothing more than simple opening and closing of the abdomen the "cure" rate would have been the same. Fortunately the operation recommended by the authors is bad enough to ensure that no gynaecologist who has clinical insight and experience is likely to perform it.—I am, etc.,

London, W.1

ALECK BOURNE.

Sexual Disorders in Women

SIR,—In Dr. Joan Malleison's valuable and interesting paper (December 22, 1951, p. 1480) and in subsequent correspondence I have found no reference to the subject of cervical sensation. In performing vaginal examinations I have observed frequently that the patient lies still and relaxed so long as the cervix is not touched, but the instant the finger comes into contact with the antero-inferior surface the respirations deepen and quicken and the patient is obviously sometimes deeply disturbed. So often has this been my experience that I have come to regard the vaginal wall as being normally relatively insensitive, and have concluded that during intercourse the essential factor in obtaining satisfactory orgasm is the impact of the glans penis upon the antero-inferior surface of the cervix.

Hence failure of the woman to obtain an orgasm may be due to two very common factors, malposition of the cervix, such as occurs in uterine retroversion and prolapse, and the use of contraceptive appliances which prevent the tip of the penis from making contact with the cervix.—I am, etc.,

Winfrith, Dorset.

P. R. BOUCHER.

Music While You Operate

SIR,—The idea of "Music While you Work" (*Journal*, January 12, p. 102) for the benefit of patients under local analgesia was anticipated by some 20 years by my esteemed friend Mr. R. H. Paramore. When operating with local or spinal analgesia at the hospital of St. Cross, Paramore would have the gramophone, and later the wireless playing in the theatre to allay the patient's anxiety. He claims great success for this method.—I am, etc.,

Rugby.

W. J. BOLD.

Anaesthetic Explosions

SIR,—It is the fashion to-day to blame static electricity as the cause of anaesthetic explosions, and even to examine the anaesthetist's shoes for charges of electricity. Not so recently, explosions occurred under open ether when diathermy or the electric cautery was used in operations on the nose and throat, with invariably fatal results. Our more recent explosions appear to be due to the more abundant use of *pure oxygen*, in anaesthesia, in oxygen tents, and

to overcome the anoxaemia caused by temporary respiratory paralysers.

The manufacturers of pure oxygen are aware that escaping oxygen coming into contact with grease will cause an explosion, and accordingly advise that grease must not be used at the junction of the oxygen cylinder with the anaesthetic apparatus. It is reasonable, therefore, to assume that grease on the patient's face or at the junction of the mask with the patient's face will be liable to cause an explosion, perhaps just as readily.

I went into this matter some 20 years ago with Professor F. G. Donnan, of University College, London, asking him to analyse the gas in an oxygen cylinder because a long flame had shot out from the cylinder junction of a dentist's anaesthetic machine and completely wrecked the glass spittoon some three feet away. Professor Donnan pointed out the fact that pure oxygen plus grease will cause the type of explosion I described.

If we are to cut down the number of deaths from explosion caused annually wherever pure oxygen is directly applied, the answer would seem to lie in supplying the oxygen already diluted with a suitable proportion of nitrogen. The manufacturers could no doubt co-operate in this matter. We require the highest proportion of oxygen in a nitrogen-oxygen mixture which will not fire readily when forced against greasy materials. (I suggest the use of nitrogen, because this gas is already being supplied to occupy the empty spaces in the self-sealing petrol tanks of aircraft.) If the manufacturers supply us with 1/5 oxygen to 4/5 nitrogen, we shall be perfectly safe from oxygen explosions, but already have our natural source of supply. Cylinders will probably have to contain between 60 to 80% oxygen mixed with air to combine safety with usefulness.—I am, etc.,

Slough.

N. C. HYPER.

Night Pain with Fractures

SIR,—The diagnosis of minor fractures at times can be difficult, and to those of us who have no x-ray facilities to hand an accurate clinical diagnosis is all the more important. Dr. J. B. Marshall (January 19, p. 163) brings to light an observation of very practical significance. This symptom of night pain I have found, when the question of fracture is being considered, can be applied to a fairly wide field in the realm of minor injuries and can often give a clue in the right direction.

A minor crush injury of the foot, such as is caused by a heavy object falling on the dorsum of the foot, which produces a limping patient with a foot swollen, bruised, tender, and fairly immobile, may leave one in doubt of the presence of a fracture. In this type of case the question can often be settled fairly conclusively from the history of night pain. A disturbed night is almost always indicative of fracture.

In the last year I have seen seven such cases. Four gave a clear history of night pain, and a radiograph showed the presence of fracture or fractures of the small bones of the foot. Those in which there was no night pain gave normal x-ray appearances.

In August, 1951, I attended a boy of 10 years who had slipped off the kerb and injured his left ankle. Seen the following day, he complained of little pain and had no signs of fracture. The ankle appeared sound apart from tenderness on dorsiflexion of the foot and tenderness over the medial malleolus. The previous night's rest had been considerably disturbed by pain. X-ray examination demonstrated a linear fracture of the lower end of the tibia.

A case of fractured clavicle in a boy of 8 years was encountered in December, 1951—presenting a picture similar to the cases described by Dr. Marshall. The x-ray examination was carried out on the strength of the history of night pain.

From the experience of these cases briefly described and of several others encountered, I feel that this symptom of night pain is worthy of consideration. As to the method of its production, might it not be due to relaxation of

muscle spasm when the patient drops off to sleep, producing involuntary movement at the fracture site—a mechanism similar to that which produces "starting pains" in joint tuberculosis?—I am, etc.,

Arrochar, Dunbartonshire.

J. MACKINTOSH.

SIR.—Dr. J. B. Marshall's observation in his letter (January 19, p. 163) is a true one, but is by no means confined to children with this fracture. Patients of any age with a painful condition in the shoulder region have more pain at night, presumably because most of us like to sleep on the side and to change our position in bed frequently. It follows that any patient with a painful shoulder, be it broken or frozen, is much better treated erect and ambulant; while at night sleep is least disturbed in a sitting position with plenty of pillows. Although this position is comfortable, it may not be always tolerable in the average English bedroom in winter.—I am, etc.,

London, S.E.1.

M. PICKERING PICK.

Traumatic Autografting

SIR.—For some time it has been recognized that wounds caused by high-velocity projectiles can, on impact, turn the firmer tissues of the body into secondary missiles. It is, however, rarely that these secondary missiles, when embedded elsewhere in the body, survive as living tissues. Usually they are either absorbed or encapsulated as foreign bodies. Recorded cases of traumatic autografts are not common, although a few cases of traumatic homografts of doubtful accuracy can be found in the literature. The case recorded below is of a soldier, aged 25, who was wounded during the Normandy landings by a land mine.

The extent of his injuries was the traumatic amputation of his right leg above the ankle, a wound on the right side of his chin, and two smaller wounds in the shoulder. He was admitted to a casualty clearing station, where a fresh amputation was performed and the facial wound was dressed. He was then evacuated, via a maxillo-facial unit, back to the U.K., arriving approximately 48 hours after his injury. It was then possible to assess more carefully the full nature of his injuries, and the following report was made.

The amputation stump was found to be quite healthy, although there was a tendency to haematoma formation. The face was inspected, and a large jagged bursting type of wound was found on the right side of the chin (Fig. 1). It did not involve the buccal cavity, and the alveolar margin was in continuity. The wound itself was very soiled with vegetation, and was found to contain a mass of fibro-tendinous material. A tendon, running across the wound, firmly embedded and alive, was the subject of much speculation, and it had apparently been blown out from beneath the jaw on the left side. Small portions of the mandible had also been broken off from its lower margin. The dead tissues were cut away and loose pieces of bone removed. No foreign bodies were found. A radiograph at this stage had shown a considerable number of bone fragments overlying the mandible.

A week later he was transferred to a maxillo-facial unit, where Sir Harold Gillies operated 13 days after wounding. Under thiopentone and cyclopropane anaesthesia the whole wound edge

FIG. 1.

FIG. 2.

was carefully excised and a deep pocket found in the right cheek, level with the angle of the mouth. In this pocket there were portions of a toe or toes complete with tendons, skin, bone, and joints. One of the tendons (extensor hallucis longus) had been previously seen lying over the symphysis menti and had been thought to be a tendon displaced from the neck, possibly the digastric. There was no bony damage to the mandible, but the periosteum was stripped off. The whole wound was very quiescent and only necrotic where a portion of the toe was presenting in the wound and looking like (and previously taken for) a sloughing portion of the cheek. Just below and behind the symphysis menti there was a brass screw, which was presumably from the mine. All foreign tissue was removed.

The patient was evacuated to a general hospital 17 days after the operation, by which time the facial wound had completely healed (Fig. 2).

It was considered at the time that this case was a remarkable example of the efficacy of penicillin, in that a previously unsterilized toe could successfully survive as an autograft.

I wish to thank Sir Harold Gillies for permission to record this case.

—I am, etc.,

London, W.C.2.

J. M. ROBERTS.

Cough Fracture in Late Pregnancy

SIR.—With reference to Dr. J. W. Poulley's letter (January 19, p. 162), a few years ago a patient of mine fractured the eleventh rib (left side) about midway between the tubercle and the tip while coughing during advanced pregnancy. The pain was immediate, and the fracture was confirmed by radiograph. She had old healed tuberculosis of the left lung. Radiography at that time showed much calcification and contraction of the upper zone.—I am, etc.,

Birmingham.

W. M. CHESNEY.

Shortage of X-ray Films

SIR.—Perhaps I may comment on the letters by Drs. R. Montgomery and W. A. Bellamy (December 29, 1951, p. 1584) complaining of waste of x-ray films in the Medical Research Council trial of antibiotics in pneumonia, reported in the *Journal* of December 8, 1951 (p. 1361). The trial was planned well before the present shortage of films became apparent and in fact was completed before the shortage became at all acute. Once such a trial has begun it is essential to keep to the original protocols. I think we would all agree that in most cases of pneumonia it is unnecessary to take x-rays so frequently, and in many cases it is unnecessary to have a film on admission, but surely there is a great deal of difference between the requirements of ordinary clinical practice and those of planned research. In clinical research one must obtain as much information as possible and make it as precise as possible.

On a purely clinical level I would disagree with Dr. Bellamy's suggestion that physical examination is all that is required before pronouncing a patient recovered from his pneumonia. The final x-ray, after physical signs have disappeared, is the only one which I regard as quite essential in a straightforward case of pneumonia. Over and over again this film will reveal abnormalities which have not been suspected on clinical grounds. Over and over again I have patients referred to me with chronic respiratory disease which might have been prevented if the trouble had been recognized by an x-ray taken at the stage when the clinical manifestations of the pneumonia had apparently subsided.

I should point out that these are my personal views and do not necessarily represent those of my colleagues on the Medical Research Council Subcommittee on Pneumonia.—I am, etc.,

Edinburgh, 9.

JOHN CROFTON.

SIR.—I was most interested in your remarks (January 12, p. 94) about wasteful tomographic procedures. I have frequently noticed that full-size 12 in. by 15 in. tomograms are being taken, where a film area of 6 in. by 7 in. would have

been quite sufficient to cover the area in question. In order to confirm or exclude cavitation in a certain area it is difficult to reduce the cuts, but surely economies in width and height are possible without detriment to accuracy. A very simple device of covering three parts of a large film with a radio-opaque plate, and centering the beam on the affected area only, makes it possible to tomograph four cuts on one film, and this has the added advantage that four successive cuts can be inspected next to each other at one viewing-box.—I am, etc.,

Wolverhampton.

E. POSNER.

Dead or Alive?

SIR,—In an article on "Suicide, Accident, or Murder?" (September 15, 1951, p. 661) Dr. Keith Simpson states, "Stethoscopic examination for the heart sounds is the only really reliable test [of death]: if there is no heart beat for four or five minutes eventual survival is impossible." At the end of the same paragraph he says, "... striking recoveries have ensued after long periods of apparently suspended animation in cases of electrocution."

Presumably a long period means more than four or five minutes, and apparently suspended animation includes no discernible heart beat, so I feel he has contradicted himself. I should be glad to know if any of your readers have personal experience of cases of apparent death from electric shock where the heart beats were indiscernible by the stethoscope under good hearing conditions for more than five minutes and yet the patient recovered. Two such cases are reported by Professor Jellinek in his book, *Dying, Apparent Death, and Resuscitation*, but I have been unable to obtain any direct evidence of other cases after writing to a number of authorities in different countries. On the available evidence, however, it does seem unwise to certify a man dead following electric shock, after failure to hear heart sounds for five minutes.—I am, etc.,

Wellington, C.I.

T. O. GARLAND.

Tablet Test for Urinary Chloride

SIR,—The valuable paper by Dr. W. H. Taylor (November 10, 1951, p. 1125) on the fallacies of the Fantus test may discourage clinicians from relying upon this estimation, which, in the case of many small hospitals, may be the only guide available. However, if the clinician bears in mind the errors likely to occur, it is surely better to carry on using the test than to have none at all.

As an attempt to minimize the technical errors, the reagents may be combined together in tablet form, thus dispensing with pipetting of the silver nitrate solution. I have found a convenient formula for the tablets to be as follows: potassium chromate 10 mg.; silver nitrate 1.46 mg.; excipient to 1 gr. (65 mg.). The test is performed in a small thick glass test-tube on 10 drops of urine plus approximately 10 drops of water. Tablets are added and crushed with a glass rod until the pink-brown end-point is reached. Each tablet is equivalent to 1 g./litre urinary chloride. The test appears to be quite as accurate as the conventional method and is well received by the nursing staff, for there is less pipetting, with a consequent decrease, for example, in pipette breakage rate.

A report of a detailed investigation into the technical aspects of this test will be published elsewhere.—I am, etc.,

Preston.

E. B. LOVE.

Fantus Estimation of Urinary Chloride

SIR,—May I comment upon the criticisms made by Dr. H. L. Marriott (November 24, 1951, p. 1284) of my paper (November 10, 1951, p. 1125)? My purpose was simply to record some of the errors that may arise from the commencement of a Fantus estimation to the giving of treatment on the basis of its result. It would be most

unfortunate if this work were in any way to be interpreted as detracting from the valuable contributions of Dr. Marriott in this field.

Dr. Marriott believes the Fantus estimation to be more accurate than my experiments show it to be. He quotes, in his support, work of which no experimental details appear to be available. It is difficult, therefore, to make any comment except to reiterate that the estimation has been found to be inaccurate to the extent indicated in my paper when performed on urine specimens passed up to four hours previously. There is little likelihood of these results being caused by contaminated solutions or by dirty test-tubes, as Dr. Marriott suggested might be the case. As the inaccuracies of the Fantus estimation tend mainly to yield high results, it is not surprising that the actual errors quoted in my table were all on the high side.

My paper also showed that the longer urine stands the more inaccurate is the Fantus estimation likely to be. It was for this reason that my experiments were performed on urine passed within four hours. However, Dr. Marriott (1951) writes:

"The main control observations which should be instituted in every case of potential or actual dehydration and maintained until all danger has passed, are eight-hourly measurements of urine volume and of urinary chloride concentration. . . . When an eight-hourly check is in progress all specimens passed during the period should be mixed. . . ."

While not disagreeing with this advice, it is clear that if urine is allowed to stand for eight hours it is likely to cause errors in the Fantus estimation at least as great as those occurring within four hours. Furthermore, it appears from Dr. Marriott's letter that the unpublished work to which he refers in support of his views was performed "with freshly passed urine"—in other words there is some doubt, from the data available, whether he has in fact checked the accuracy of the Fantus estimation under the circumstances in which he recommends its use.

Dr. Marriott makes the further point that the errors to which the Fantus estimation is subject do not affect its usefulness provided one accepts his limit of abnormally low urinary chloride concentration as 3 g. NaCl/litre. Whatever numerical limit is accepted, though, if an estimation is sufficiently inaccurate to push the value above this limit when it should be below it, a wrong conclusion may be drawn and perhaps because of it a patient given the wrong treatment.

Dr. Marriott also considers that the speed with which the Fantus test can be performed justifies its use. Even if it can be performed in two minutes the highly accurate and trustworthy Volhard estimation can be completed within 10. Are there ever circumstances in hospital practice where this maximal difference of eight minutes could justify the use of a potentially misleading estimation at the expense of one more trustworthy? The Volhard estimation can be quite easily carried out in the side-ward. It needs but two solutions, distilled water, a conical flask, and a 5-ml. graduated pipette, and it estimates only halides however long the urine has been standing or whatever other anions are present.

Turning next to the usefulness of urinary chloride estimations, Dr. Marriott has somewhat misinterpreted my views. After my arguing that to be useful urinary chloride estimations should reflect the body's need of sodium ions there occurs in my paper the following sentence:

"In most patients in whom problems of fluid balance arise in hospital this relationship between urinary chloride concentration and the body's requirement of sodium ions still holds good, but exceptions arise."

I then go on to add further to Dr. Marriott's own list of exceptions. Somehow, however, Dr. Marriott has inferred that urinary chloride estimations are "undesirable," and, having launched this argument, has devoted a whole column of your *Journal* to destroying it. In fact, it will be found that Dr. Marriott's views and my own are not so very far apart. He writes of the usefulness of urinary chloride concentrations that "better definition of limitations will come as knowledge grows." Surely he will admit that my addition of two further instances to his own list of limitations is contributing to this growth. The contributions of Mr. Wilkinson and his colleagues and of Dr. Spencer, which I quoted, also make for "better definition" and do not deserve to be dismissed by Dr. Marriott as "a few disparaging references." Recently Denton (1951) has described further limitation of the usefulness of urinary chloride estimations.

I am sorry that Dr. Marriott should have found my article to contain only "negative criticism" which "is not difficult" and to give "no positive help at all to the inexpert." It was not, of course, my purpose to present an account of salt and water

therapy. He fails, however, to note my recommending the use of the Volhard estimation in preference to that of Fantus, and ignores my concluding statement, "Never to rely upon a urinary chloride estimation alone as a basis for salt therapy but to take into account also the clinical signs and the plasma chloride (or, better, sodium) concentration."

It is possible also that those readers who use the Fantus estimation would welcome the knowledge that the test is less likely to be accurate when using infected urine or urine which has stood for some time. Perhaps, too, the description of further groups of patients in whom urinary chloride analyses afford no reliable guide to salt therapy may be of some positive help to clinicians who face these problems.

In conclusion it is possible that the divergent views of Dr. Marriott and myself may be attributed to the fact that we have worked upon dissimilar groups of patients. My experience has been confined to post-operative patients and to patients unconscious from head injury, cerebral vascular accident, meningitis, or diabetes. From the work of Wilkinson *et al.*, Spencer, and Denton, it would appear that the incidence of circumstances in which urinary chloride estimations fail to reflect the body's sodium requirements is sufficiently high in these patients to call for the modification of schemes of treatment.—I am, etc.,

Oxford.

Educating the Public about Cancer

SIR,—We in this country should be grateful to Drs. T. A. Watson and O. D. Beresford (January 12, p. 107) for their encouraging letter on this subject. In our experience in the south-west of England the public are eager enough to be enlightened, but opinion in the medical profession is divided. The main objections are that education will depress the spirits of the people by creating a cancer phobia, that if a campaign is inaugurated it will lead to a rush of patients to the doctors' surgeries even when they have nothing the matter, and that the early signs are so varied and dubious that education is impossible. We are confident that if the information given follows sensible lines and not too much is attempted there is a good answer to all these objections. The cancer phobia already exists; if women are assured, as they can be assured, that odd pains in the breast without a lump do *not* mean cancer, and that two-thirds of cases treated early will be alive and well three to five years later and many of them much longer still, their fears will be replaced by astonishment and hope. To the overworked doctor who fears a sudden rush we would say: Which would you prefer, to send 10 women away happy by telling them they have not got cancer, or to have to attend a hopeless case to give morphine every day for six months, because she showed you her breast in July when she ought to have come in January? To meet the third objection, it would be well in the first place to concentrate attention on three well-defined clinical pictures—the painless lump in the breast (which may not be cancer after all), irregular uterine bleeding in a woman past 40, and a sore on the lip, tongue, or in the mouth which does not heal in a fortnight.

In the south-west region records of cancer cases have been collected from all the main hospitals for four or five years past, and a near-hundred per cent follow-up has been maintained. Our records show that, of women knowing they have a lump in the breast, only 38% come up for treatment within three months, and 32% delay for over a year. Of women with uterine cancer, 34% come up within three months, and 38% delay for a year or more. Doctors may think that published figures of cancer "cures" are too optimistic, only the exceptionally fortunate statistics being put on record. We can assure them that in this area, served by about 30 surgeons and radiotherapists, 69.5% of cases of carcinoma of the breast treated in the first stage are alive and well three years after, and 56% after five years. Very few stage 3 or stage 4 cases survive that length of time. Figures for cancer

of the uterus are similar. Death from advanced cancer is often a long and painful business, and we are sure it can be avoided in many patients.

What form might education take? One simple way would be for leaflets advising patients with lumps in the breast, irregular bleeding, or persistent sores in the mouth to consult a doctor. These could be distributed in doctors' surgeries, women's institutes, etc. It might be wise, in view of the difference of opinion in the profession, for a trial to be made in one or two areas in the country to see whether the delay period in seeking advice and the number of cancer deaths could after, say, three years be reduced by a vigorous local campaign of public education, of which the keynote should be not fear but hope.—I am, etc.,

Bristol.

A. RENDLE SHORT.

Congenital Defects in Mongols

SIR,—The paper by Dr. Martin Bodian and his colleagues (January 12, p. 77) on congenital duodenal obstruction and mongolism was of great interest. I recently surveyed the congenital defects occurring in a consecutive series of 45 mongols who came to necropsy in this hospital in the period 1938 to 1951. The chief findings, which I quote by kind permission of Dr. H. S. Baar, were as follows:

Cardiac abnormalities (excluding patency of the foramen ovale and patency of ductus arteriosus) in 28.

Congenital duodenal obstructions in six.

Harelip and hydronephrosis in two each.

Meckel's diverticulum, partial absence of pancreas, horseshoe kidney, meningocele, congenital hydrocephalus, syndactyly, congenital dislocation of hip, absence of radius, in one each.

The findings in the six cases of mongolism with duodenal obstruction are briefly given in the Table.

Sex	Age at Death	Early Symptoms	Necropsy Findings
F	8 weeks	Vomiting aet. 10 days	Partial stenosis at junction of 2nd and 3rd part duodenum. Peritoneal bands narrowing 3rd part. Small patency of foramen ovale
F	6 days	Vomited blood aet. 2 days	Suprapapillary duodenal atresia. Patency of pars membranacea of patent interventricular septum
M	8 "	Vomiting from birth	Suprapapillary duodenal atresia. Subacute pancreatitis. Small patency of foramen ovale
M	9 "	Vomiting from birth	Complete atresia of 3rd part of duodenum. Perforated gastric ulcers with peritonitis
M	6 weeks	Projectile vomiting in 3rd week of life	Partial suprapapillary stenosis of 2nd part of duodenum, 1 cm. in length
F	16 days	Vomiting from birth	Partial suprapapillary stenosis of 2nd part of duodenum. Gross dilatation of 1st part

During the same period 15 infants with intrinsic obstructions or atresia of the duodenum (excluding those with malrotations or mesenteric abnormalities alone) were admitted to hospital. The high proportion of mongols—6 out of 15—fully bears out Dr. Bodian's contention.—I am, etc.,

The Children's Hospital, Birmingham.

L. M. ROSE.

Diabetic Gangrene

SIR,—The instructive paper by Dr. A. Grunberg, Mr. H. L. Davies, and Dr. J. L. Blair (November 24, 1951, p. 1254) invites brief comment. Nowadays many of these cases need never resort even to "conservative" surgery if large doses of alpha tocopherol are given them. Our first observations on this subject have recently been substantiated by Butturini,¹ and others, of course, have testified to its value in diabetic arthritis²⁻⁴ and in ordinary arteriosclerotic gangrene.⁵—We are, etc.,

PENICILLIN**your chronic bronchitics need**

The perennial problem

of

effectively treating chronic bronchitis—and many other chest conditions*—finds its solution in **ESTOPEN**. This recently discovered penicillin derivative has proved remarkably effective in clearing chronic suppurating lung troubles. Sputum volumes fall dramatically, penicillin-sensitive organisms disappear, and the whole clinical picture improves appreciably.

These effects are due to the unique ability of Estopen to achieve the fundamental aim of all penicillin treatment—to bring therapeutic amounts of the antibiotic to the site of infection.

 Research Laboratories • Manufacturers of medical products and foods • Associate companies or agents in almost every country of the world

We are glad to announce—

that the Research Workers of our parent firm, following their long experience in the chemistry of steroids, have successfully carried out one of the most complicated syntheses, that of

CORTISONE

Our Laboratories, which were among the first to manufacture oestradiol, have thus maintained their leading position in the field of hormone chemistry.

Manufacture of Cortisone on an industrial scale has already been undertaken, and although only limited quantities will be available during 1952, every effort is being made to increase production.

For even
greater security
in Sulphonamide
Therapy

'Cremotresamide' reduces the incidence of crystalluria — the primary factor causing renal complications in patients undergoing sulphonamide therapy.

'Cremotresamide' produces and maintains highly effective blood levels.

'Cremotresamide' combines low toxicity, excellent tissue distribution and good therapeutic efficiency.

'Cremotresamide' is particularly acceptable to children, but will be found useful in all age groups.

'Cremotresamide' contains 0.5 G. of the mixed sulphonamides in each teaspoonful — Sulphadiazine 0.2 G., Sulphamerazine 0.1 G., Sulphacetamide 0.2 G.

Descriptive literature, clinical package and practical dosage card gladly forwarded on request. Sharp & Dohme Ltd., Hoddesdon, Herts.

Sulphonamide
Suspension

Rapid Cure of Actinomycosis

SIR,—In view of the usually protracted and unhappy progress of a patient with actinomycosis it seems worth recording the rapid recovery of a boy with actinomycosis of the neck who was treated recently.

The boy, aged 14, was first seen on September 18, 1951, with a history of swelling on the left side of the neck of four weeks' duration. It had been steadily increasing in size, but was relatively painless except when he moved his head sharply or when the swelling was touched. Examination showed an area of infiltration on the left side of the neck extending from the anterior border of the sterno-mastoid to the midline and from the mandible to the sternum. He was admitted to hospital as a case of actinomycosis on September 20, and treatment started with "aureomycin" capsules (two six-hourly), potassium iodide 10 gr. (0.6 g.) thrice daily, and penicillin 1,000,000 units daily. Seven days later the area of infiltration was much less, with definite fluctuation in the centre and pus obviously approaching the skin. Incision released pus with typical "sulphur granules." Bacteriological examination revealed *Streptomyces actinomycosis*. On October 22 the incision had healed, and there was no evidence of thickening. All medication was stopped and the patient was discharged.

He has been followed up at the out-patient clinic since, and was last examined on December 23, 1951, when there was no evidence of recrudescence. Progress was rapid after incision of the fluctuating area, and medication might have been stopped earlier. Knowing so little about the dosage necessary for this condition, however, it was decided to continue treatment until no residual thickening could be found.—I am, etc.,

Mauchline, Ayrshire.

A. H. SANGSTER.

Westergren and Wintrobe Methods Compared

SIR,—I was much interested in the article by Dr. David Gilmour and Mr. A. J. Sykes (December 22, 1951, p. 1496) on the subject of the relative merits of the Westergren and Wintrobe methods of estimating the sedimentation rate. I find myself substantially in agreement with them.

I did a great deal of work on the subject on behalf of a committee of the Empire Rheumatism Council, the results being embodied in several publications, notably in Fletcher's *Medical Disorders of the Locomotor System* (Edinburgh, 1947). The main conclusion was that the Westergren method was easily the best for the purpose. While it is a little hard to see how the errors described by your writers arise, there can be no doubt that, where rates are increased, the longer the tube is the better. In the short tubes the onset of packing at the bottom of the tube occurs earlier, with the result that lower values are obtained. Where rates are normal, however, the column length seems to be immaterial so long as it exceeds 25 mm., the results being the same in tubes of all lengths (and, incidentally, in all bores also so long as the tubes are kept strictly vertical, small bores being more sensitive to this).

The great virtue of the Wintrobe tube was supposed to be that it lent itself to ready estimation of the cell volume by centrifuging the tube. This was done either before the test was set up, the cell volume being corrected by withdrawing plasma, or after sedimentation had occurred, the results being corrected for cell volume by means of a table. It is hard to see how such correction can be justified even on theoretical grounds when the mechanism of the test is considered. The test depends upon the size of rouleaux of cells falling through plasma of relatively constant viscosity, and a shortage of cells might be expected to produce smaller slower-falling rouleaux rather than the contrary. In actual practice, we have always found that all the evidence pointed to the conclusion that correction for cell volume was wrong. Thus we have had two cases of aplastic anaemia, one very severe (untransfusable on account of reactions): in both these cases the sedimentation rate has been constantly normal for years. Such a finding accords well with our experience of over 20,000 estimations of sedimentation rate, that correction for cell volume could not be justified.—I am, etc.,

London, W.1.

J. W. SHACKLE.

Toxic Chemicals in Agriculture

SIR,—It has been stated that there are no sequelae to poisoning by organic phosphorus compounds used as insecticides. In August, 1951, three people developed symptoms of acute poisoning following exposure to a new substance in this group, *bis-mono-isopropyl aminofluorophosphine oxide*. Although these symptoms responded in the usual way to the administration of atropine, two patients developed flaccid paralysis involving all four limbs, which came on slowly in the third week after the acute phase of the illness. The lower limbs were affected first and most severely and have not yet recovered fully. The cases will be described in detail in a report which is being prepared for publication. The purpose of this letter is to draw attention to the fact that paralysis resembling that which follows poisoning by tri-*ortho*-cresyl phosphate may also occur after poisoning by other organic phosphorus compounds. Petry (*Zbl. Arbeits-med.*, 1951, 1, 86) records a case of similar paralysis in a man exposed repeatedly to parathion in the fumigation of greenhouses.—We are, etc.,

London, E.1.

POINTS FROM LETTERS**Incontinence in Women**

Dr. B. E. W. STALLARD (Hereford) writes: Dr. S. Brennan (January 12, p. 110) asks for cases of incontinence in women. Some years ago an unmarried lady about 50 consulted me for dribbling of urine, over one week. On examination the vagina was closed by a thick soft hymen, with a tiny opening about the mid-point from which urine was trickling. There had never been any injury. I dissected off two-thirds of the hymen and put in a few stitches and she had no further trouble after a slight *B. coli* cystitis cleared. The condition was clearly congenital.

Homes for Incurable Children

Dr. IAN G. WICKES (Stock, Essex) writes: In a letter from the Invalid Children's Aid Association (January 19, p. 161), Dr. A. White Franklin and others emphasize the lack of suitable homes for incurable children with gross physical deformities, and they remark "that, legally, public authorities should provide accommodation for children of this kind, but all too often the bed for the long-term case is just not there." The lack of accommodation for the mentally defective child is also serious and the cause of very great hardship in countless homes, where the whole family is penalized and humiliated by the constant care and attention which a severe mental defective requires. The waiting-list for institutional treatment is several years long, and very little is done to help the weary mother in the interim. From time to time I have taken such a child into a children's ward to give the mother a rest, but experience has taught me to limit the proposed period of admission to a predetermined number of days or weeks. . . . Surely the time has come for an inquiry on a national scale into the demand for and supply of institutional accommodation for mentally and physically incurable children.

Incontinentia Pigmenti

Dr. W. L. CALNAN (Wroughton, Wilts) writes: I have read the interesting article on this subject by Dr. A. White Franklin (January 12, p. 75). The statement that no case has yet been recorded in England is not quite correct. Dr. Henry Haber published a case in 1948. Also I published a report of a child with congenital hemiatrophy in the *Journal* of July 9, 1949 (p. 56), and I described associated cutaneous abnormalities, which I now know to be characteristic of incontinentia pigmenti. I am grateful to Dr. Haber for drawing my attention to the correct diagnosis (*Journal*, July 23, 1949, p. 230). This child, like Dr. White Franklin's patient, was born and lives in Hertfordshire.

Dr. H. HABER (London, N.W.6) writes: In his paper (January 12, p. 75) Dr. A. W. Franklin, reviewing the literature, stated that "no case has yet been recorded in England." May I draw Dr. Franklin's attention to the fact that I showed the first case of incontinentia pigmenti to the Dermatological Section of the Royal Society of Medicine on April 15, 1948 (*Proc. roy. Soc. Med.*, 41, 759) ?

Obituary

Sir ARTHUR GASKELL, K.C.B., O.B.E., F.R.C.S.
(Surgeon Vice-Admiral, ret.)

Surgeon Vice-Admiral Sir Arthur Gaskell, Honorary Surgeon to the King and Medical Director-General of the Royal Navy from 1927 to 1931, died on January 12 at Fareham, aged 80.

Arthur Gaskell was born at Dartmouth and studied medicine at University College Hospital, where he qualified in 1892. A year later he entered the Royal Navy as a surgeon. Several years of service at the Royal Naval Hospital at Chatham gave him opportunity to develop his surgical skill, and he became a Fellow of the Royal College of Surgeons in 1899. In 1900 he had charge of the surgical section of the advanced base hospital at Leu-Kung-Tao in the Boxer rebellion. His good work there was recognized by his special promotion to staff surgeon in 1902. Four years later he became fleet surgeon. He took a special interest in physical training and in the teaching of first aid, and while at the Cape station he had a booklet on first aid printed and distributed at his own expense. Some years later at the request of the Admiralty he wrote a primer on first aid which became the official textbook on this subject in the Royal Navy. In 1913 he took the D.P.H., a year before his appointment as first director of medical studies and professor of hygiene at the new naval medical school organized at the Royal Naval College, Greenwich. At the outbreak of war in 1914 he was responsible for the fitting out of the hospital ship *Soudan*, and a month later he became the principal medical officer of the Royal Naval Division and was in charge of the medical unit in the Gallipoli campaign, being mentioned in dispatches and appointed C.B. From 1916 to 1919 he was in charge of the Royal Naval Hospital at the Cape of Good Hope and was awarded the O.B.E. for his valuable services there.

At the end of the war Gaskell was promoted to surgeon-captain, and he served again at the Royal Naval Hospital, Chatham, until 1923, when he was appointed medical officer in charge of the Royal Naval Hospital, Plymouth, and promoted to the rank of surgeon rear-admiral. Three years later he was promoted to surgeon vice-admiral and succeeded Sir Joseph Chambers as Medical Director-General of the Navy, a post which he held until his retirement in 1931. Gaskell was appointed Honorary Surgeon to the King in 1928 and created K.C.B. two years later. After his retirement he served on the Committee on the Medical Branches of the Fighting Services under the chairmanship of Sir Warren Fisher.

Sir Arthur Gaskell is survived by his widow and a son and a daughter. His elder son was killed in action in 1944.

HAZEL H. CHODAK-GREGORY, M.D., F.R.C.P.

Mrs H. H. Chodak-Gregory (née Cuthbert), children's physician at the Royal Free Hospital from 1927 to 1946, died in London on January 12 at the age of 66. Hazel Howard Cuthbert studied medicine at the London School of Medicine for Women, where she was quickly recognized as an outstanding student. She graduated M.B., B.S. in 1911 and two years later proceeded M.D. In 1915 she obtained the M.R.C.P. After qualifying she held various resident appointments, including that of

resident medical and surgical officer at the Children's Hospital, Birmingham. She had always a great love of children and knew from the first that her main interest was in their medical care. She took a wide view of this, realizing that it involved a knowledge of social and preventive medicine as well as clinical skill and experience. In 1916 she was appointed acting assistant physician to the Royal Free Hospital. Three years later this appointment was confirmed and she became assistant physician, being the first woman physician to be appointed to the honorary staff. In 1927, when the children's work was separated from general medicine and the Riddell wards for children were opened, she became children's physician to the hospital, a post which she held until her retirement in 1946. She was also for many years physician to the Children's Hospital, Shadwell. In 1935 she became the second woman to be elected a Fellow of the Royal College of Physicians.

Dr. Gregory was always interested in the teaching of students (by whom she was affectionately known as "Mrs. C.-G.") and in their general welfare, and she took her fair share in all the work of the hospital and medical school. She was for some years chairman of the medical committee of the hospital and was vice-dean of the medical school during 1933-8. At the outbreak of the second world war, when the clinical students were posted to the Three Counties Emergency Hospital at Arlesey in Bedfordshire, she was acting dean for the duration. She was resident physician in charge of the division under the E.M.S., with care of children's wards and charge of general medical beds.

Dr. Gregory married towards the end of the first world war and leaves one son, who is in the medical profession.

O. R. and G. B. write: Dr. Gregory was always a stimulating teacher and had the great gift of expecting the best from everyone. At the same time she had a tolerant outlook and a strong sense of values, which enabled her to overlook the shortcomings of others; the few criticisms she made were constructive and never unkind. It was at Arlesey that she became so well known and loved by all with whom she worked. She made an outstanding success of this difficult appointment, integrating the work as a whole and organizing with enthusiasm the social as well as the clinical side of the hospital. She was naturally shy and reserved, and this at times made her appear somewhat unapproachable, but those who came to know her and to be admitted to her friendship realized her great charm, her integrity, and her unselfish readiness to help others. Throughout her life she accepted difficulties with philosophy and courage, especially when she faced so magnificently the losing battle against ill-health.

F. G. writes: The death of Mrs. Chodak-Gregory is a personal loss to many old students and colleagues at the Royal Free Hospital. We came to know her best at Arlesey, where she was senior physician during the war, and to recognize her absolute integrity and sound judgment. Those of us who were residents at Arlesey will always remember the evenings spent with her in friendly and stimulating discussion, and we shall always be grateful for her encouragement and wise counsels.

H. E. SYMES-THOMPSON, M.D., M.R.C.P.

The death of Dr. H. E. Symes-Thompson on January 18 removes from the ranks of medicine one who will long be remembered by his colleagues and friends for his unfailing kindness, geniality, and sympathy for others. He represented the third generation of a family distinguished in the study and practice of disease of the chest. His grandfather, Theophilus, was one of the original

members of the staff of the Brompton Hospital, and was followed by his son in a similar role.

Henry Edmund Symes-Thompson was born in London in 1873. After school at Winchester, he continued his studies at Christ's College, Cambridge, and later at St. George's Hospital. At Cambridge he took the Natural Science Tripos, graduating B.A. in 1894 and M.A. in 1898. He qualified in medicine in 1900, proceeding M.D. in 1903, and becoming M.R.C.P. in the same year. After holding resident appointments at St. George's, the Westminster, and the Brompton hospitals, he was elected in 1905 to the staff of the Royal Northern Hospital, and later to the Royal Chest Hospital, City Road. When he retired from the active staff he became consulting physician to the latter hospital in 1934, having completed 29 years' service with the two hospitals.

He continued for some years in private practice, and among other appointments he was for many years physician to the Royal National Hospital for Consumption, Ventnor. He practised in London through the war years, but his life was saddened by the untimely loss of his eldest son, Edmund, who was killed in an air raid while on duty at his hospital.

Symes-Thompson's personality was an eminently cultured one. His manner was courtly, if diffident. His outlook on life was religious, and for many years he had been examiner to the Society for the Propagation of the Gospel. His approach to medicine was an academic one, and coloured by his expert use of the stethoscope. Radiological diagnosis he regarded at first with some scepticism, but he eventually made full use of the opportunities in diagnosis which it offered. He was proud to relate that the stethoscope was first used in England by Laennec when he demonstrated at the Royal Chest Hospital about 1820. He published a number of papers during his lifetime, including one entitled "The History of Tuberculosis."

Later Symes-Thompson spent much of his time at his family residence in Buckinghamshire. He was a keen cricketer and spent many of his leisure hours at Lord's. He is survived by his widow and a son and a daughter, to whom we offer our deepest sympathy.—F. E. S. W.

Dr. JAMES ADAM SMITH died at Huddersfield Royal Infirmary on November 25, 1951, at the age of 27. He studied medicine at St. Andrews University, graduating M.B., Ch.B. in 1947. After qualification he held resident posts in Stirling Royal Infirmary and Huddersfield Royal Infirmary before serving in the R.N.V.R. When he had completed his national service he became house-surgeon (obstetrics and gynaecology) at Blackpool Victoria Hospital, and obtained his D.Obst.R.C.O.G. in 1950. He then entered general practice in Huddersfield, and his untimely death cut short a promising career. Jimmy Smith's passing will be mourned by all with whom he came in contact. Our deepest sympathy is extended to his young widow.—W. S. W.

The death occurred suddenly on December 9, at the Victoria Hospital, Cork, of Lieutenant-Colonel H. E. MURRAY (late I.M.S.), of Castletownshend, Co. Cork, aged 62. A son of the late Mr. Edward James Murray, of Dundrum, Co. Dublin, Herbert Edward Murray was educated at St. Stephen's Green School and Trinity College, Dublin, where he graduated M.B., B.Ch., and B.A.O. in 1913. After a period as house-surgeon at the Royal Victoria Eye and Ear Hospital in Dublin and a trip to Australia as ship surgeon in the liner *Orontes*, he joined the R.A.M.C.

in September, 1914. From November of that year until early 1916 he served in the Ypres salient as M.O. to his battalion of the Queen's Westminster Rifles. Transferring to the Indian Medical Service, he had further war experience in the N.W. Frontier Province, and afterwards held various medical military posts in India and Hong Kong until 1925, when he transferred to the civil side of the I.M.S. in Bengal. Returning to Trinity College on study leave he proceeded M.D. in 1929 and M.Ch. in 1930. Thereafter he held a number of important appointments in Calcutta, including those of superintendent of the Presidency General Hospital, professor of midwifery and gynaecology to the Medical College, and first surgeon to the Eden Hospital. He became a Fellow of the Royal College of Obstetricians and Gynaecologists in 1940, and was created a Companion of the Indian Empire in 1944. After retiring from the I.M.S. he held the post of senior obstetrician and gynaecologist at the Leicester General Hospital for a time, but later he went back to India, where he entered into partnership with Lieutenant-Colonel Hamilton in Madras. He returned to Ireland about a year ago, settling in Castletownshend, Co. Cork, where he soon laid the foundations of a good private practice and, in addition, was appointed gynaecologist to the Victoria Hospital, Cork. In 1933 he married Lylie Frances, daughter of the late C. H. Miller, of Co. Dublin. His death at a comparatively early age will be a great loss to the district in which he had so recently settled.

Dr. FREDERICK HUGH SMITH, who practised in Leeds, Lincolnshire, and Lancashire, died on December 18 at Hemel Hempstead. We are indebted to Dr. A. P. Bertwistle for the following appreciation: Dr. F. H. Smith was in my year at Leeds University. He joined up in the 1914-18 war as soon as he could do so in a medical capacity, serving as a surgeon probationer in H.M.S. *Achates*, a destroyer. He was in the thick of the Battle of Jutland. He returned to Leeds to graduate in 1919, and later went to a rubber company in Singapore. He then came back to England to practise for a time in Leeds, but he longed for the country and went to live in Coningsby, in the delightful county of Lincolnshire, where he was thought much of, especially by the poor and aged. He was a magnificent gardener, making a success of those fastidious flowers orchids. He had many hobbies, including playing the violin and philately. He was one of the kindest of men, and had a keen sense of humour. He leaves behind a devoted wife and a married daughter.

Dr. REGINALD NICKLIN died suddenly at Luanshya, Northern Rhodesia, on January 7, aged 47. He graduated M.B., Ch.B. at the University of Birmingham in 1926, and took the M.R.C.S., L.R.C.P. conjoint diploma in the following year. He entered the Colonial Medical Service, and served in Zanzibar from 1929 to 1937, Nyasaland from 1937 to 1947, and Northern Rhodesia from 1947 to 1950, when he retired, having been provincial medical officer, Northern Province. He joined the medical staff of the Roan Antelope Copper Mines, Ltd., in Luanshya during 1950. Dr. Nicklin had all the qualities that go to make an ideal colleague and general practitioner. His unselfishness, kindness, and good humour never deserted him, and his advice was always wise and balanced. His passing is a great loss. He is survived by his widow and two sons.

Colonel A. O. B. Wroughton writes: I saw with great regret and sorrow the obituary notice of Mr. W. H. MILLER (January 19, p. 167). I first met him in Bedford in 1929 on my retiring from the Army. During my time in Bedford he was a very real friend, and I am deeply grateful for his many kindnesses to me and my wife and family. He was a splendid surgeon and physician and full of sympathy and understanding, and I deem it a privilege to have had him as a friend.

Medico-Legal

DEATH AFTER XYLOCAINE INJECTION

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

The first known example, in England of death following an injection of "xylocaine" was the subject of an inquest by the Mid-Northants coroner on December 12, 1951.

The deceased was Miss Monica Annie Atkins, aged 27, of Gayton, Northants. She was known to have suffered from pulmonary tuberculosis since 1946 and had been an in-patient at Creaton Sanatorium since December 15, 1949. A two-stage thoracoplasty had been performed on her on October 9 and November 20, 1951, and parts of seven ribs had been removed to allow the left lung to collapse. She suffered much pain after the second operation and was seen on December 4, 1951, by the senior registrar of the thoracic surgery unit at Oxford, who decided that if certain simple measures failed to alleviate her pain the nerves to the affected area should be injected with a local analgesic.

On December 8, the simple measures having failed, the patient agreed to injection, and at 11.45 a.m. a paravertebral block was begun on the left side with the patient sitting up in bed. A solution of less than 1% xylocaine was used, 10 ml. to anaesthetize the skin and 70 to 80 ml. in all, and no injection was made without first testing to make sure that the needle did not lie in a blood vessel or in the spinal canal. At about 12 o'clock the patient complained of feeling faint, and was told that only one more nerve had to be injected. As she was turned on to her back it was noticed that she was talking irrationally, and 10 seconds later she had a fit, making irregular movements with her limbs. She lost consciousness, and her pulse could no longer be felt. Spontaneous respiration lasted for a few minutes while she was given oxygen and nikethamide injections into the heart and veins, and 0.3 g. of thiopentone was given intravenously to control further fits. After another 10 minutes her heart failed again, and she died at 12.25 p.m.

At necropsy the brain was found to be symmetrical and firm. The leptomeninges and spinal cord were congested. The left lung was collapsed and on section showed tuberculous involvement. There was chronic pleuritic thickening, and on the left side slight paravertebral subpleural haemorrhage. There were old and relatively recent subcutaneous haemorrhagic zones in the left and right axillary regions, especially on the left side, approximating to the areas of the hypodermic puncture marks.

There were no traces of xylocaine or its breakdown products in specimens of cerebrospinal fluid, urine, or blood.

Dr. R. M. Heggie, director of pathology at the Northampton General Hospital, who carried out the necropsy, came to the conclusion that death was caused by intravascular absorption of the xylocaine used in the paravertebral block and its subsequent cerebral medullary action. His inquiries showed that 500-600 thoracoplasties had been performed with xylocaine without accident, and indeed it had previously been used on the patient for her own thoracoplasties without untoward effects. But he said that in a recent paper quoted to him describing 130 successful thoracoplasties there was a warning about the use of xylocaine in areas where deep bruising was suspected. (An annotation on xylocaine appeared in the *Journal* of January 26, p. 211.)

A verdict of death by misadventure was recorded.

According to the *Report on the Work of the Central Midwives Board*, just published, the M.R.C. Committee investigating the use of trichlorethylene in childbirth is still unable to recommend its use by midwives on their own. None of the inhalers submitted for trial has been found satisfactory. Since April, 1950, midwives have been able to give pethidine, although it is on the Dangerous Drugs List, but the regulations are to be changed to impose a limit to the total amount they can hold.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on December 15, 1951, the following degrees were conferred:

D.M.—J. J. Pritchard, B. F. A. Swynnerton.
B.M.—J. P. Blandy, D. H. Malan, E. T. C. Tewson, D. H. Eaton, P. D. Grant, I. S. L. Loudon, K. F. R. Schiller, J. A. Smith, R. D. Weeks, W. T. Barrett, I. O. Carlisle, W. M. Jordan, C. V. Mann, D. F. Woodhouse, H. B. Calwell, B. T. Bond, M. S. Compton, F. S. Keddie, W. F. C. Kennedy, M. A. Fenton, A. M. Stobie, P. R. Walker, M. W. Sweet-Escott, K. F. M. Thomson, W. Whitechurch, C. F. Bolton, J. M. Davies, Hélène V. Goodman, Jean Ginsburg, G. T. Haysey (in absence).

Dr. H. M. Sinclair has been elected a member of the Committee of the Museum of the History of Science until Michaelmas Term, 1954.

J. R. P. White (Queen Anne's School, Caversham) has been elected to a Nuffield Medical Scholarship at Lady Margaret Hall; C. Streatfeild (Ashford School for Girls, Kent) to an H. T. Gerrans Exhibition in Medicine at Somerville College; and C. A. Baker (College Scholar, and Croydon High School, Girls' Public Day School Trust) to a Scholarship in Medicine at St. Hugh's College.

UNIVERSITY OF CAMBRIDGE

Bryan Harold Cabot Matthews, C.B.E., Sc.D., F.R.S., has been elected Professor of Physiology in the University, as from January 1, in succession to Dr. E. D. Adrian, O.M., P.R.S., who is now Master of Trinity College. Professor Matthews was born on June 14, 1906, and was educated at Clifton College and at King's College, Cambridge, of which he has been a Fellow since 1929. He graduated B.A., with first-class honours in physiology, in 1927 and proceeded M.A. four years later. The degree of Sc.D. was conferred upon him in 1937. He held a Beit Memorial Fellowship for medical research from 1928 to 1932, and was assistant director of research in physiology in the University from 1932 to 1947. When the readership in experimental physiology was established in 1947 he was appointed to the post. He was a British member of the 1935 International High Altitude Expedition for Physiological Research. He was director of the R.A.F. Physiological Research Unit in 1940 and director of the R.A.F. Institute of Aviation Medicine from 1944 to 1946. Professor Matthews was elected F.R.S. in 1940 and appointed C.B.E. in 1944.

UNIVERSITY OF ST. ANDREWS

Professor Earl R. Loew, Professor of Physiology in the University of Boston School of Medicine, has been appointed Visiting Lecturer for 1952 in the Faculty of Medicine of St. Andrews University. Professor Loew will hold his lectureship in the Department of Pharmacology and Therapeutics, Medical School, Dundee, for the month of September.

The following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—D. M. Alexander, R. H. Arnold, J. S. Bain, H. J. Barclay, D. G. P. Brown, Betty K. Dean, H. R. Foreman, Elizabeth H. L. Hay, R. L. Kelly, C. W. Law, Margaret E. J. Leckie, R. A. C. Lundie, D. M. McKerrell, H. A. Maher, R. Moncrieff, G. I. Rooney, Joan E. Warren, Eleanor T. Winter, Ariane G. M. Wiseman.

UNIVERSITY OF GLASGOW

The following degrees were conferred on January 12:

M.D.—A. J. V. Cameron, W. A. Dewar, K. C. Grigor, A. G. Macgregor, F. C. Rodger, T. Young, C.B., O.B.E., K.H.P., Major-General.

CH.M.—D. St. C. L. Henderson, J. Hutchison.
M.B., CH.B.—S. Alexander, I. R. G. Barclay, J. D. Begg, A. W. Bennie, J. W. Browning, R. Budge, J. C. Burgess, J. D. Caldicott, Evelyn M. Camrass, Doreen M. Chisholm, A. S. Cooper, L. MacD. Craig, D. Craigen, A. B. B. Culhane, J. Curley, G. M. Currie, E. Diamond, E. D. Docherty, J. N. Docherty, A. L. C. Duncan, T. H. Fairbairn, P. Forrester, W. V. Fowler, J. R. Freeland, R. A. Garden, I. A. Gibson, H. P. Gillespie, W. D. S. Hepburn, J. Houston, R. D. Hunter, Mary G. S. Hyslop, J. Lambie, W. K. Lawson, I. A. Levy, R. H. MacKay, Moira R. Mackie, T. C. G. McKirdy, M. MacLean, W. McLellan, A. G. W. McLeod, A. McQuater, W. I. Martin, R. H. D. Miles, J. Mitchell, G. P. Moffat, L. MacG. Munro, T. H. Neilson, J. M. Paterson, J. Rintoul, W. P. Ritchie, N. MacN. Robertson, C. C.

Quantity **DEMANDS** Quality

The daily dosage of P.A.S. varies between 12 grammes and 18 grammes, but in all cases it is exceptional in the *large amount taken* and the *length of treatment*. Purity is recognised as of importance even in drugs given in a dose of 0.01 grammes. How much more vital is it when 18 grammes is taken every day for many months? In the manufacture of 'PARAMISAN SODIUM' purity is the over-riding consideration.

Therefore specify

'PARAMISAN SODIUM'

PHYSICIAN,*heal thyself!*

These are times of worry and stress, in fact, Peptic Ulcer times. You are rushed off your feet, eating and sleeping irregularly, worried about your patients' troubles, with no time to consider your own health.

Your stomach is tired too, and perhaps has grown irritable with a diet of hurried sandwiches and frequent cups of tea. **PEPTALAC** contains pre-digested protein, thus taking much of the load from your gastric juice. Starch has also been subjected to an independent treatment to bring about a degree of dextrinization to aid assimilation. The Milk fat remains unaltered.

In this way, we practically digest your food for you — all you have to do is to absorb it. It tastes good, too.

May we suggest that you try some, and if you find it does the trick, prescribe it for your patients. We shall be pleased to send you a clinical sample of **PEPTALAC** and literature on request to our Medical and Research Dept.

Guildford, Surrey

4811

of 1950 and 1949, respectively. The rate for 1951 was 22.9, compared with 22.7 in 1950 and 1949.

The deaths registered in the quarter numbered 121,759, representing a rate of 11.0 per 1,000 population, compared with 135,359 and a rate of 12.3 for the corresponding quarter of 1950. The total number for the year 1951 was 548,918, and the rate was 12.5, compared with 11.6 in 1950. The increase was concentrated in the first quarter of the year, during which there was a widespread influenza epidemic.

Census Changes.—Population figures obtained at the 1951 census show that there are now 160 great towns (population over 50,000) in England and Wales instead of 126, and 17 principal towns (population over 30,000) in Scotland instead of 16. Therefore the 1952 figures for deaths, births, and stillbirths in these countries, published weekly in our Table, cannot be accurately compared with those for 1951, which are printed in italics. The 160 great towns in England and Wales have a population about 10% higher than in the 126.

Medical News

Health Service Charges.—The Chancellor of the Exchequer, Mr. R. A. Butler, announced in Parliament on January 29 that a shilling charge on prescriptions is to be introduced. This would bring in £12m. in a full year. There will also be charges for some appliances, such as surgical belts and boots, hearing-aids, and wigs. Amenity beds in hospitals will cost more. Where there is hardship help will be given in meeting the new charges. In the dental service the patient is to pay the cost of treatment up to £1.

Guide to London Social Services.—The London Council of Social Services has recently published a little handbook intended to present a picture of the various organizations offering social services in the London area. The different types of services provided by statutory and local bodies are briefly described, and also the new social services—Family Allowances Act, National Health Services Act, and so on. A history of social services seems rather out of place in so short a pamphlet, and the space it occupies could more profitably have been filled with further useful addresses. As it is, the appendix gives a few, but for the most part tells the reader that they may be found in the telephone directory. However, the *Handbook to the Social Services in London* does summarize in a small space an account of the services available, and, even if addresses have to be looked up, the place to find them is given. It is obtainable from the council at 7, Bayley Street, London, W.C.1, price 7½d. post free.

Artificial-eye Specialists.—An association of artificial-eye specialists has been formed at 15, Woburn Square, W.C.1, to look after the interests of these technical practitioners.

Yugoslav Rehabilitation Team.—A group of doctors and medical auxiliaries from Yugoslavia have been studying rehabilitation in this country and the U.S.A. during the past six months. Plans for their tour were made with the help of W.H.O. The team, consisting of three doctors, a nurse, a social worker, an occupational therapist, a remedial gymnast, and a secretary, was under the leadership of Dr. Zotoeic. On January 21 the Yugoslav Ambassador and Madame Brilej gave a reception on the eve of the team's return to Belgrade, where they will establish a rehabilitation unit which it is hoped will eventually serve as a training centre for workers from Yugoslavia and other countries.

Sir Edward Mellanby Honoured.—The Royal Swedish Order of the North Star (Commander, First Class) has been conferred on Sir Edward Mellanby, formerly secretary of

the Medical Research Council, in recognition of his services to medical research in Sweden. The decoration was presented to him by the Swedish Chargé d'Affaires, M. Unger, on January 21 at the Swedish Embassy in London.

What's What in International Medicine.—The Council for the Co-ordination of International Congresses of Medical Sciences issues a quarterly bulletin giving details of the council's aims and achievements, information about many international medical and para-medical organizations, and a valuable calendar of international congresses to be held in 1952 and later. The bulletin will be sent free of charge to universities, medical organizations, etc., from Unesco House, 19, Avenue Kleber, Paris, 16^e. Otherwise it costs 2s.

Publication Difficulties of Scientific and Medical Journals.—The *British Medical Journal* is not alone in receiving an unprecedented flood of contributions and in struggling under a heavy burden of printing and paper costs. Many scientific journals are experiencing identical difficulties, and the Royal Society has set up a publications commission, with Professor S. Zuckerman (professor of anatomy, Birmingham University) in the chair, to discuss the whole problem with the Master Printers Federation and the printing trades unions, and to consider whether the Treasury might be asked to make a bigger grant in aid of publications. New and cheaper methods to replace ordinary printing will also be considered. Varitype, for instance, is a way of printing from typescript which avoids all the expense and delay of hand-setting of type by experienced compositors. The Society finds that costs have at least doubled since before the war, that the number of suitable papers submitted for publication in the *Proceedings* is going up by at least 20% annually, and that the publication delay, which used to be a maximum of six months, is now approaching the two years already experienced by some journals. The great increase in papers is attributed to the enormous increase in the numbers of science graduates since 1945, and the flood is expected to grow as more and more complete their first research. It has also become more important professionally to be the author of a list of published papers.

Any Questions?—The first printing of *Any Questions?* has now sold out, and the book is being reprinted. It is hoped to be able, in about six weeks' time, to supply those who have already ordered copies. Those requiring copies, but who have not yet ordered them, are urged to make early application to the Publishing Manager, B.M.A. House, Tavistock Square, London, W.C.1.

50 Years' Progress in Medicine.—Over 300 pages of text, a complete index, and 32 illustrations, all for 15s., make *50 Years of Medicine* a valuable book to have. A symposium surveying the progress of medicine and surgery over the first half of the century was published in the *Journal* in 1950, and the articles are now obtainable in book form. Much useful information is contained in the book, which is of interest to medical and lay readers alike. It may be bought from booksellers or direct from the Publishing Manager (post free) at B.M.A. House, Tavistock Square, London, W.C.1.

Emergency Bed Bureau at Liverpool.—This service completed its third year of operation on September 30 last, and its latest annual report shows that in the year it handled over 12,000 applications for admission to hospital. Nearly 500 of these were from hospital out-patient departments, the rest being from general practitioners. 92.8% of the cases were admitted, and beds found for a further 560 patients were refused by them. Teaching hospitals were able to take in 900 cases at the Bureau's request. Admission of elderly patients (60 years old and over) was the most difficult, as was to be expected.

Emergency Bed Service: Applications and Admissions.—During the seven days ending January 28 the number of applications made by doctors to the London Emergency Bed Service for admission of patients was 1,165, of whom 85.4% were admitted.

COMING EVENTS

Broussais Hospital Courses.—Three courses will be held in Paris at the Broussais Hospital from May 18 to May 31; the subjects covered will include renal pathology (four days), allergic diseases (six days), and three *journées médicales* will be devoted to papers on a wide range of subjects, such as the treatment of acute leukaemia, allergic migraine, and the use of A.C.T.H. The registration fee is 2,500 francs; the number of participants is limited to 150, and early application is advised. Full details may be obtained from Dr. R. Wolfromm, 96, rue Didot, Paris, 14^e.

International Diabetes Federation Congress.—People interested in the congress to be held at Leyden, the Netherlands, during the second week of July, 1952, are requested to apply for a prospectus to Dr. R. D. Lawrence, 149, Harley Street, London, W.1.

Tuberculosis Conference.—The twelfth conference of the International Union against Tuberculosis will be held at Rio de Janeiro, under the presidency of Professor Manoel de Abreu, from August 24 to 27. The subjects for discussion are immunity and tuberculosis, treatment and prognosis in minimal pulmonary tuberculosis, and organization and results in regard to the tuberculosis campaign of mass surveys. Members of the union may take part in the conference without paying an admission fee. Physicians who do not belong to the union may apply for membership of the conference, and should send in their applications exclusively through their Government or national association, who are alone qualified to forward such applications. All requests for information concerning the scientific discussions should be sent to Professor Etienne Bernard, secretary-general, 66, Boulevard St. Michel, Paris. All requests concerning the organization of the congress should be sent to the secretariat of the conference, 197, Avenida Mem de Sa, Rio de Janeiro. Applications from physicians in Great Britain should be sent through the N.A.P.T., Tavistock House North, Tavistock Square, W.C.1.

SOCIETIES AND LECTURES

A fee is charged or a ticket is required for attending lectures marked ●. Application should be made first to the institution concerned.

Monday

CAMBRIDGE MEDICAL SOCIETY.—At Physiology Lecture Theatre, Addenbrooke's Hospital, Cambridge, February 4, 8.15 p.m., annual general meeting. "The Use of Antabuse in the Treatment of Alcoholic Delinquents and Criminals," film to be shown by Dr. Erik Jacobsen (Copenhagen).
PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury Square, London, W.C.—February 4, 7.30 p.m., "The Work of the Privy Council," by F. J. Fernau.

Tuesday

ANGLO-JEWISH ASSOCIATION.—At 33, Seymour Place, London, W., February 5, 8.30 p.m., "Jews in Medicine," by Dr. W. J. O'Donovan.
BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., February 5, 5.30 p.m., "Methods of Research in Social Medicine," by Dr. Alice M. Stewart.
● **INSTITUTE OF DERMATOLOGY,** Lisle Street, Leicester Square, London, W.C.—February 5, 5.30 p.m., "Sweat," by Dr. C. A. Keele.
ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—February 5, 5 p.m., "Prevention of Shock and Anaemia in Trauma," Arris and Gale Lecture by Mr. A. R. Clarke.
WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck Street, London, W. (entrance for lectures 40, Marylebone Lane, W.)—February 5, 5.30 p.m., "Intracranial Abscess," by Mr. G. C. Knight.

Wednesday

● **INSTITUTE OF DERMATOLOGY,** Lisle Street, Leicester Square, London, W.C.—February 6, 5.30 p.m., "Mycology—Histoplasmosis: *Coccidioidomycosis*," by Dr. R. W. Riddell.
INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., February 6, 4.30 for 5 p.m., "Treatment of Gonorrhoea," by Dr. W. N. Mascall.
MANCHESTER MEDICAL SOCIETY: SECTION OF MEDICINE.—At Physiology Theatre, Medical School, Manchester University, February 6, 4.30 p.m., "Modern Methods of Treatment of Pulmonary Tuberculosis from the General Practitioner's Angle," by Dr. M. J. Greenberg.

OXFORD UNIVERSITY.—At Radcliffe Infirmary (Maternity Department Lecture Theatre), Oxford, February 6, 5 p.m., "Insulin Tumours of the Pancreas," Litchfield Lecture by Professor J. Morley.

Thursday

BRITISH POSTGRADUATE MEDICAL FEDERATION.—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., February 7, 5.30 p.m., "Contributions in the Twentieth Century to the Practice of Health," by Professor J. M. Mackintosh.
FACULTY OF HOMOEOPATHY.—At Royal London Homoeopathic Hospital, Great Ormond Street, London, W.C., February 7, 5 p.m., "Indigestion from a Surgical Standpoint," by Mr. Harold Dodd.
HARVEIAN SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—February 7, 8.15 p.m., "Low Backache," discussion to be introduced by Mr. P. H. Newman and Mr. Leslie Williams.
● **INSTITUTE OF CHILD HEALTH,** Hospital for Sick Children, Great Ormond Street, London, W.C.—February 7, 5 p.m., "Abdominal Surgery in Childhood," by Professor Ian Aird.
● **INSTITUTE OF DERMATOLOGY,** Lisle Street, Leicester Square, London, W.C.—February 7, 5.30 p.m., "The Reticuloses in Relation to Dermatology," by Dr. J. O. Oliver.
LIVERPOOL MEDICAL INSTITUTION.—At Royal Southern Hospital, Caryl Street, Liverpool, February 7, 2.30 p.m., afternoon clinical demonstration.
MANCHESTER MEDICAL SOCIETY: SECTION OF ANAESTHETICS.—At Staff House, Manchester University, February 7, 8.15 p.m., short papers.
● **MOTHERS' CLINIC,** 108, Whitfield Street, London, W.—February 7, 2.30 p.m., lecture and demonstration (on living models) on Contraceptive Technique by Marie C. Stopes.
ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, London, W.C.—February 7, 5 p.m., "Surgical Treatment of Banti's Syndrome," Hunterian Lecture by Professor A. H. Hunt.
ROYAL INSTITUTION, 21, Albemarle Street, London, W.—February 7, 5.15 p.m., "Respiratory Pigments," by Professor H. Munro Fox, F.R.S.
ST. ANDREWS UNIVERSITY.—At Lecture Theatre, Materia Medica Department, Medical School, Small's Wynd, Dundee, February 7, 5 p.m., "Recent Work on Blood Groups and their Clinical Significance," by Professor D. F. Cappell.
ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—February 7, 4.30 p.m., lecture-demonstration in neurology by Dr. D. Williams.

Friday

● **INSTITUTE OF DERMATOLOGY,** Lisle Street, Leicester Square, London, W.C.—February 8, 5.30 p.m., "Developmental Abnormalities," clinical demonstration by Dr. R. M. B. MacKenna.
● **INSTITUTE OF DISEASES OF THE CHEST AND INSTITUTE OF CARDIOLOGY.**—At London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., February 8, 5.30 p.m., "Surgical Aspects of Cyanotic Congenital Heart Disease," by Mr. T. Holmes Sellors.
OSLER CLUB.—At Royal College of Surgeons of England, Lincoln's Inn Fields, London, W.C., February 8, 7.45 p.m., "Hippocrates in Ancient and Modern Times," by Dr. W. N. Mann; "On Translating Hippocrates," by Mr. John Chadwick; "Amputations—Hippocrates and Modern Times," by Mr. Leon Gillis; "Hippocrates and Periodicity in Life and Disease," by Dr. J. H. D. Webster.
OXFORD UNIVERSITY.—At Magdalen College, Oxford, February 8, 5 p.m., "The Neurophysiological Basis of Mind," Waynflete Lecture by Professor J. C. Eccles, F.R.S.

Saturday

SOUTH-EAST METROPOLITAN REGIONAL TUBERCULOSIS SOCIETY.—At Kettlewell Hospital, Swanley, Kent, February 9, 10.30 for 11 a.m., general meeting. "The Pulmonary Circulation in Lung Disease," lecture by Dr. Paul Forgacs.

APPOINTMENTS

AARON, F. E., M.B., Ch.B., D.C.P., Assistant Pathologist, Stockport and Buxton Group, Manchester Regional Hospital Board.
BROWN, G. LAING, M.D., D.P.H., Consultant, Physician-Superintendent, Bucknall Hospital, Stoke-on-Trent.
DALZELL-WARD, A. J., M.R.C.S., L.R.C.P., D.P.H., Deputy Medical Director, Central Council for Health Education, Tavistock House, Tavistock Square, London, W.C.1.
DONOVAN, WILLIAM, M.B., M.A.O., M.R.C.O.G., Obstetrician-Gynaecologist to the Counties of Sligo, Leitrim, and Donegal, Eire.
HUTTON, JAMES, M.D., D.P.H., Medical Officer of Health, School Medical Officer, and Port Medical Officer of the Borough and County of Poole and Medical Officer of the Poole area of Dorset.
LONDON, JOSEPH JOHN, M.B., B.Chir., Medical Officer for Corporation Staff Welfare, etc., Public Health Department, City of Birmingham.
LUM, L. C., M.B., B.S., M.R.C.P., M.R.A.C.P., Physician-Superintendent (Consultant) at Nayland Sanatorium, East Anglian Regional Hospital Board.

Are Vaginal Tampons Prejudicial to Health?

An Investigation* concerned with the bacteriology of vaginal flora following the use of internal tampons was undertaken at the request and with the co-operation of the visiting gynaecologists to a London Women's hospital.

It is gratifying to find that this investigation confirms earlier work carried out in America and gives further support to the claim that Tampax can be confidently recommended as a convenient, comfortable and safe form of sanitary protection.

** Tampax tampons were used in this investigation.*

EXTRACTS FROM THE REPORT:—

- ★ "Smears and cultures taken before and after each period showed no appreciable change in the bacterial flora of the vagina."
- ★ "None of the volunteers acquired monilia or trichomonal organisms during the period of study or developed erosions or vaginitis as a result of using the internal tampon."
- ★ "There was no aggravation of the condition or delay in healing following the use of tampons in the patients who had cervical erosions."
- ★ "In each case the underlying cause responded to treatment, and did not recur, which proves that the internal tampon does not act as an irritating foreign body."
- ★ "The rate of healing compared favourably with four control cases in which the perineal pad was used."
- ★ "The glycogen content was uninfluenced by the use of tampons."
- ★ "There was no appreciable alteration in the pH in the pre- and post-menstrual phases."
- ★ "Volunteers who had not previously used tampons stated that they did not cause the irritation usually found with the perineal pad."
- ★ "There was no evidence that vaginal tampons are prejudicial to health."

British Medical Journal, 1, 24 (1952)

Literature and professional samples of Tampax will be sent on request to:

MEDICAL DEPARTMENT, TAMPAX LIMITED, 110 JERMYN STREET, LONDON, S.W.1

ELASTOPLAST BANDAGING TECHNIQUE

In the treatment of varicose ulcers . . . careful bandaging is essential in order to achieve the best results.

Seepage of discharge beneath a bandage may be prevented by cutting small holes in the bandage as illustrated.

Cotton wool, held in place over holes by a further strip of Elastoplast, absorbs discharge. See illustration opposite.

Elastoplast TRADE MARK elastic · adhesive **BANDAGES**

Besides **ELASTOPLAST ELASTIC ADHESIVE BANDAGES** other T. J. Smith & Nephew bandages and products available for use in the treatment and after-care of varicose conditions are **ELASTOCREPE · ELASTOLEX · ELASTOWEB · DIACHYLON/ELASTOCREPE · VISCOPASTE · ICHTHOPASTE · COLTAPASTE · ELASTOPLAST PLASTERS · PARAGON SPONGE RUBBER · JELONET**. Full details from the Medical Division, T. J. Smith & Nephew Ltd., Hull.

Outside the British Commonwealth, Elastoplast and Elastocrepe are known as Tensoplast and Tensocrepe respectively.

MANCHESTER REGIONAL HOSPITAL BOARD.—Consultant Ear, Nose and Throat Surgeon, Blackburn Hospitals Centre, J. Evans, M.D., F.R.C.S.Ed. Consultant Neuro-Surgeon, Salford Royal and Crumpsall Hospitals, H. A. Maslowski, M.D., F.R.C.S.Ed.

NORTH-EAST METROPOLITAN REGIONAL HOSPITAL BOARD.—Part-time Consultant Psychiatrist, St. John's Hospital, Chelmsford, Winifred M. Burbury, M.B., B.S., D.P.M. Part-time Consultant Psychiatrist, Prince of Wales's Hospital, J. C. Sawle Thomas, M.R.C.P., D.P.M. Part-time Consultant Psychiatrist, St. Clement's Hospital, P. H. Tooley, M.D., M.R.C.P., D.P.M. Part-time Assistant Psychiatrist (S.H.M.O.), Chelmsford Child Guidance Clinic, and Wulhamstow Child Guidance Clinic, J. E. G. Vincenzi, M.R.C.S., L.R.C.P., D.P.M. Part-time Assistant Venereologist (S.H.M.O.), Prince of Wales's Hospital, R. Atlas, M.D. Part-time Consultant Venereologist, Oldchurch, Chelmsford and Essex, and Tilbury and Riverside (Tilbury Branch) Hospitals, E. M. C. Dunlop, M.D., M.R.C.P. Full-time Assistant Anaesthetist (S.H.M.O.), Chase Farm Hospital, Edith de Winter, M.D., D.A. Maximum Part-time Consultant Anaesthetist, North Middlesex Hospital, W. F. O'M. Doherty, M.B., B.Ch., D.A.

O'SULLIVAN, JOHN THOMAS, M.B., D.P.H., Medical Officer, Rathmullan (Co. Donegal) Dispensary District.

SOUTH-WEST METROPOLITAN REGIONAL HOSPITAL BOARD.—Whole-time Consultant Chest Physician, Croydon Area, R. H. J. Fanthorpe, M.D., M.R.C.P. Whole-time Assistant Chest Physician (S.H.M.O. Grade), Kingston and Mortlake Area, R. Hambridge, M.R.C.S., L.R.C.P. Part-time Consultant Child Psychiatrist, West Sussex Child Guidance Service, F. T. Shadforth, L.R.C.P.&S.Ed., D.P.M. Part-time Consultant Psychiatrist, Belmont Hospital, F. O'D. Finigan, M.B., B.S., M.R.C.P.Ed., D.P.M. Part-time Consultant Dermatologist, Lambeth and Wandsworth Groups of Hospitals, M. Fewell, M.B., B.Chir., M.R.C.P. Part-time Consultant Dermatologist, Farnham Group of Hospitals, J. Morgan, M.D. Part-time Consultant Pathologist, Battersea and Putney Group of Hospitals, R. S. Ralph, M.R.C.S., L.R.C.P., D.P.H. Part-time Consultant Orthopaedic Surgeon, Epsom Group of Hospitals, H. H. Kennedy, F.R.C.S.Ed. Whole-time Assistant Physician and Deputy Physician-Superintendent (S.H.M.O. Grade), Dorking General Hospital, E. G. Wilkins, M.D., M.R.C.P., D.T.M.&H. Registrar to Medical Department, South-western Hospital, Z. J. Prokopowicz, M.B., Ch.B. Senior Registrar to Surgical Department, Redhill County Hospital, J. P. Turney, M.B., B.S., F.R.C.S. Senior Registrar to Anaesthetic Department, St. Helier Hospital, R. A. Green, M.B., B.Chir., D.A. Registrar to Group Pathological Laboratory, St. Mary Abbots Hospital, A. Swan, M.B., B.S. Senior Registrar to Radiological Department, St. James' Hospital, A. W. R. Jenkins, M.B., B.Ch., D.M.R.D. Senior Registrar to Pathological Service, Portsmouth and Isle of Wight Groups of Hospitals, J. A. U. Morgan, M.B., B.S., M.R.C.P. Senior Registrar to Ophthalmological Department, Southampton Eye Hospital, G. Bennett, M.B., Ch.B., D.O.M.S. Registrar to Obstetric and Gynaecological Department, Mayday Hospital, Mary G. Coyle, M.B., Ch.B. THOMAS, WILLIAM EDGAR, M.R.C.S., L.R.C.P., Part-time (Temporary) Medical Officer of Health, Ammanford Urban District Council, Carmarthenshire.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Fulton.—On December 24, 1951, at Manygates Maternity Hospital, Wakefield, to Lesley, wife of Dr. John B. Fulton, Alverthorpe Grange, Wakefield, Yorks a son.

Jepson.—On January 16, 1952, at Invercargill, New Zealand, to Joan (formerly Blacklock), wife of Dr. L. Frank Jepson, a son—Charles Robert.

Semple.—On January 21, 1952, at the Middlesex Hospital, London, W., to Dr. Alison Semple, wife of Dr. Robert Semple, a daughter.

MARRIAGES

Masters—Newland.—On January 5, 1952, at St. Mary's Church, Bromley, Kent, Edgar James Masters, M.B., B.S., to Jean Newland.

DEATHS

Battersby.—On January 15, 1952, in hospital, at Taplow, Bucks, John Battersby, M.B., Ch.B., L.D.S., of 17, Regent Street, Nottingham.

Browne.—On January 17, 1952, at The Lindens, Farnborough Park, Hants, Edward George Browne, C.B., C.M.G., L.R.C.P.&S.I. & L.M., D.P.H., Major-General, R.A.M.C., retired, aged 88.

Crawford.—On January 22, 1952, at Nuffield House, Guy's Hospital, London, S.E., Hugh Grogan Crawford, O.B.E., M.C., M.R.C.S., L.R.C.P., of Ryland House, Cannock Wood, Rugeley, Staffs.

Edwards.—On January 13, 1952, in hospital, following an accident, Francis Henry Edwards, M.D., M.R.C.P., of "Brightlands," Reigate, Surrey, aged 80.

Heath.—On January 19, 1952, at Otley, Suffolk, James Glover Heath, M.R.C.S., L.R.C.P.

Hort.—On January 25, 1952, at 19, Fitzjohns Avenue, London, N.W., Frederick Aylmer Hort, M.D.

Kelly.—On January 27, 1952, at 329, Roundhay Road, Leeds, Christopher Peter Kelly, L.R.C.P.&S.I. & L.M., aged 90.

Lamb.—On January 24, 1952, Ralph Lamb, M.R.C.S., L.R.C.P., L.D.S., of Low Roof, St. George's Road, Hightown, near Liverpool.

Menon.—On January 15, 1952, at St. Joseph's Hospital, Whalley Range, Manchester, Maniketh Vythi Menon, M.R.C.P.Ed., D.P.H., D.T.M., of 524, Oldham Road, Manchester, Lancs, aged 60.

Millard.—On January 14, 1952, at the Royal Infirmary, Manchester, Peter McDonald Millard, L.R.C.P.&S.Ed., L.R.F.P.S., of 191, Slade Lane, Levenshulme, Manchester, Lancs.

Purvis.—On January 19, 1952, in London, John Allen Spottiswoode Purvis, M.B., B.Ch., aged 53.

Renshaw.—On January 13, 1952, Graham Renshaw, M.D., of St. Michael's, Hale, Cheshire, and 30, St. Ann's Street, Manchester, aged 79.

Saunders.—On January 16, 1952, Charles Howard Saunders, M.B., B.Ch., of The Hill, Hedge End, Southampton, aged 84.

Singer.—On January 20, 1952, at 25, Milton Avenue, Sutton, Surrey, Hugh George Singer, M.R.C.S., L.R.C.P., aged 38.

Smith.—On January 19, 1952, at his home, "Thrusleys," Middlesbrough, near Wakefield, Yorks, Charles Holden Smith, M.B., Ch.B., aged 58.

Stallard.—On January 19, 1952, at his home, Pennock, Morin Road, Paignton, Devon, John Prince Stallard, M.D., formerly of Oxford Road, Manchester, aged 94.

Thomson.—On January 14, 1952, at his home, 10, Southfield Avenue, Barnston, Midlothian, Thomas Lauder Thomson, M.D., D.P.H., aged 74.

Vawdrey.—On January 16, 1952, at West Worthing, Marion Ethel Unwin Vawdrey, L.R.C.P.&S.Ed., L.R.F.P.S., formerly of East Horsley, Surrey.

Any Questions ?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Tuberculous Glands in the Neck

Q.—Could you tell me the latest views on the treatment of tuberculous glands in the neck? Are streptomycin and para-aminosalicylic acid (P.A.S.) worth trying? Has deep x-ray therapy a place? When should surgical block dissection be advised?

A.—In tuberculosis, even more than other illnesses, it is important to treat the patient, not the disease. In nearly all cases, tuberculosis of lymph glands is not an isolated lesion but one manifestation of a widespread disease, and the main principle of treatment is to overcome the infection either by general measures or by specific remedies. Streptomycin and P.A.S. are emphatically worth trying. Surgical measures are called for to evacuate pus or to remove avascular caseous material which the drugs cannot reach. There is no place for x-ray therapy. A surgical block dissection, which implies removal of glands as part of a block of connective tissues, is not advised. Exceptionally, when the disease appears to be localized to a small group of glands they may be dissected out.

Analgesics for the Nose

Q.—What analgesics are best for use in the nose before instrumentation? What are the dangers?

A.—If by instrumentation is meant such manoeuvres as the passage of a Eustachian catheter or antrum, cannula, the best analgesic is undoubtedly a 5% or 10% aqueous solution of cocaine hydrochloride, applied with a fine spray. This is not only a rapidly acting and effective analgesic, but also a powerful vasoconstrictor. If deeper analgesia is desired the nose may be packed with ribbon gauze or cotton-wool pledgets which have been soaked in a mixture of equal parts of the cocaine solution and 1 in 1,000 adrenaline and then squeezed out.

The chief danger of cocaine is its toxicity; the susceptibility of patients varying considerably. The danger is avoided by using the minimum amount, by avoiding swallowing, and by prior administration of a barbiturate in persons known to be susceptible. A remote risk is the development of cocaine addiction. Because of these dangers, or when cocaine is unobtainable, less toxic substitutes are used, chiefly 2% amethocaine hydrochloride. These are slower acting, and are not vasoconstrictors, so a little ephedrine or adrenaline solution should be added to them.

Further information may be found in *Diseases of the Nose, Throat, and Ear*, by Jackson and Coates (Saunders, Philadelphia, 1929), and in the most recent edition of *Diseases of the Nose and Throat*, by Thomson and Negus (Cassell, London, 1948).

The Egg and the Sperm

Q.—How long can (a) the ovum and (b) spermatozoa survive in the human female genital tract? How reliable are the answers to this question?

A.—(a) There is no exact information available on the time during which the ovum remains capable of being fertilized. Hartman (1939), however, considers that all the experimental data on higher vertebrates, including monkeys, indicate that the unfertilized ovum survives for only a few hours; these data are so concordant that they may be accepted as applying to women also.

(b) The viability of spermatozoa in the healthy vagina is very limited, and live spermatozoa are seldom found eight

hours or more after intercourse. Their viability in the cervical canal depends upon the stage of the menstrual cycle: the cervical mucus in the early part of the cycle is scanty and "hostile" so that sperm penetration is poor and viability is usually confined to a few hours; in the immediately pre-ovular phase, the mucus is normally copious and easily penetrated by spermatozoa which survive for long periods; very shortly after ovulation, cervical hostility reappears and the survival time drops to a few hours. In general, it may be taken that spermatozoa will survive for 12 to 24 hours in receptive mucus, but there are reports of much longer survival times—e.g., Cary (1936) found spermatozoa present 80 hours after intercourse.

The reports on viability within the uterus and tubes are very variable: Joël (1942) found viable spermatozoa within the uterus at 25 hours, but in the tubes all were dead within 20 hours of coitus; Hünner (1929) found living spermatozoa in the uterus seven days after coitus; Dührssen (1893) claimed to have found them in sealed tubes three and a half weeks after the last occasion of intercourse; and Nürnberger (1920) states that he found them in normal tubes removed 13 and 14 days after the last occasion of intercourse. It must not, however, be concluded that spermatozoa surviving for such long periods would still necessarily be capable of fertilizing ova. On the contrary, all the reliable data indicate that coitus preceding ovulation by more than 24 hours, or succeeding it by more than a very few hours, is most unlikely to result in fertilization and conception.

Schools for the Educationally Subnormal

Q.—*What provision is made under the National Health Service (or elsewhere) for the free or assisted schooling of mentally handicapped children? To whom must application be made for assistance?*

A.—The Education Act of 1944 imposes upon local education authorities (i.e., county and county borough councils) the duty of securing educational provision "for pupils who suffer from any disability of mind or body, by providing, either in special schools or otherwise, special educational treatment—that is to say, education by special methods appropriate for persons suffering from that disability."

The following extract from the latest report of the Ministry of Education is relevant (Cmd. 8244, 1951, H.M.S.O.):

"The new approach to the problems of special educational treatment and ascertainment introduced by the 1944 Act was specially important in connexion with the treatment of the educationally subnormal, the term now used to describe both those children who, before 1945, had been certified as educable mental defectives and those who had been classified as merely dull and backward. The category of educationally subnormal extends over a wide range of mental ability from the child who only needs some special help in the ordinary school to the lower limit of those who can gain benefit from education in a special school. The emphasis has thus shifted from certifying a child as 'mentally defective' (a term now confined to children who are ineducable at school) to discovering what is best for the child of subnormal ability and trying to provide this for him. For the majority the task is within the compass of the ordinary schools; nevertheless, a considerable proportion need to be dealt with in special schools. Despite substantial progress, the shortage of schools for the educationally subnormal remains the biggest deficiency in the special school system."

Under the National Health Service, the administration of mental deficiency institutions is in the charge of the regional

hospital boards, but the ascertainment of mental defectives and their supervision when they live in the community is the responsibility of the local health authorities.

Information can be obtained from the schools medical officer of the locality.

Hormone Therapy in Endometriosis

Q.—*Does endocrine therapy relieve the symptoms of pelvic endometriosis, in particular menorrhagia, metrorrhagia, and attacks of abdominal pain? If so, what scheme of treatment is advised?*

A.—The endocrine treatment of pelvic endometriosis is not very satisfactory. Massive doses of progesterone have been tried, with equivocal results. Testosterone, however, will always control symptoms temporarily, and in a big enough dose will suppress the activity of both the normal and aberrant endometrium. The difficulty is that large doses given for a long time are likely to have virilizing effects. Moreover, when treatment is suspended, symptoms usually recur. It might be worth while giving methyl testosterone 10 mg. sublingually daily for two months. This is a moderate dose, and if it gives relief and does not cause virilism it might be repeated after an interval of one or two months.

Adaptability of Infants to Changes of Climate

Q.—*What influence should climatic factors have in deciding when to let a healthy infant travel to the Tropics (West Africa)? In view of the longer period for acclimatization, is sea travel preferable to flying? At what age is the journey best tolerated?*

A.—If the child is to live on the Nigerian plateau it may be introduced at any time. The best weather in coastal regions in West Africa is roughly between November and February. The wet season should be avoided if possible. Children are not upset as a rule by flying or by sudden transition from cold to heat. Flying in the wet season, particularly in July and August, is often bumpy and unpleasant, and some stations may be difficult to reach, especially in the Cameroons. Apart from this there are no particular disadvantages in flying.

The child should be taken out as a young infant, if possible while still on the breast, as breast milk is the most sterile form of food it is likely to get. The newly weaned infant is liable to be plagued with gastro-intestinal disturbances due to changes in diet and infection, and as a general rule clean fresh milk is not available on the west coast, and powdered milk will be required. In the very young child the risk of malaria is probably slight if it receives reasonable maternal attention, drug prophylaxis, and sleeps under a net. In highly endemic regions, however, it is probably inadvisable to introduce a baby during the periods of maximum transmission.

Leopard Society

Q.—*Where can I find information on leopard societies?*

A.—On p. 76 of the book "*Any Questions?*" The book can be obtained for 7s. 6d. (postage 6d.) from the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 4499. TELEGRAMS: Aitology, Westcent, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1. on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

British Medical Association

PROCEEDINGS OF COUNCIL

Wednesday, January 23, 1952

A fully attended meeting of the Council of the Association was held at B.M.A. House, London, on January 23, with Dr. E. A. GREGG in the chair. The Council sat, with two short intervals, from 10 a.m. to 7.10 p.m.

At the outset it was agreed, on the motion of Dr. I. D. GRANT, that, apart from the recommended expenditure on the furnishing of the Hastings Hall as a new members' lounge, no decisions involving increased expenditure be taken at that meeting, and that the next meeting of Council should be for two days, one of the days to be devoted to a consideration of the financial position of the Association.

The death of a former member of Council, Dr. A. R. Thomas, of Portsmouth, was reported, and a vote of condolence with the relatives was passed.

Congratulations were accorded to the 36 members of the Association, including one member of Council (Dr. J. M. Gibson, O.B.E.), whose names figured in the recent Honours List.

A report was presented on the proceedings of the Fifth General Assembly of the World Medical Association, held recently in Stockholm.

Another report presented was from the Medical Practices Bureau, whose work in all departments increased during 1951, and the Council expressed appreciation of the work done by the Medical Director, Dr. L. S. Potter, an assistant secretary of the Association.

It was stated that it was hoped to make arrangements for the portrait of Dr. H. Guy Dain, which was recently presented to him, to be shown in Birmingham, where his Midlands friends could see it.

Appointments

Dr. Frank Gray was appointed representative to serve, by invitation, on the newly formed Dental Services Committee of the British Dental Association.

Lord Horder was appointed representative on the executive committee of the third International Congress of the Association of Gerontological Societies, to be held in Great Britain in 1954; Dr. Annis Gillie a representative to attend

a forthcoming conference of the Royal College of Nursing on problems relating to nursing requirements of the mental health services; and Dr. C. Metcalfe Brown and Dr. J. M. Gibson as delegates to the Royal Sanitary Institute Health Congress, to be held at Margate in April.

Nominations were also made, at the request of the Ministry of Health, for the appointment or reappointment of medical members on the Central Health Services Council and its several standing advisory committees.

Medical Manpower in War

The Council acquiesced in a request from the Ministry of Health that the Central Medical War Committee should continue in being for a further short period until the new organization for the control of medical manpower came into operation. The request was accompanied by an expression of appreciation from the Minister for the services rendered by that committee and by the Services Committee.

The Council also gave some consideration to the new scheme, recently approved by Ministers, which lays down the composition of the new central and local recruitment committees. It was stated that the only respect in which the Ministers have not accepted the views of the Association concerns the area committees for public health medical officers for England and Wales. On these committees for each civil defence region there are to be two medical practitioners representing county council areas, three representing county borough and non-county borough areas, and one representing urban and rural district council areas. Three of the members are to be appointed by the Society of Medical Officers of Health, and three by the associations of local authorities, after consultation with all the bodies concerned. The question of procedure for allocation of individual civilian doctors to satisfy wartime needs at home is reserved for further consultation with the profession.

The scheme for composition of the committees was accepted with the proviso that the position regarding the area committees for public health medical officers should be reconsidered in a year's time.

A resolution from the Manchester Division was considered protesting against the priority for recall to the Services being made at the expense of reserve officers who volunteered for an emergency prior to 1939.

Dr. D. F. HUTCHINSON said that the military authorities felt that they must have a certain proportion of these reserve officers, but they were trying so far as possible to reduce the number required. It was a question of planning. The Council had already in 1951 communicated a resolution very much on the Manchester lines to the Ministry of Defence and the Ministry of Health.

The Professional Intake

A request came to the Council from the East Somerset Division that an inquiry should be made into the relationship between the number of medical students accepted for training and the future requirements for doctors, so that any discrepancy which might be disclosed could be rectified as soon as possible.

Dr. WAND said that he was constantly being asked by members when the Association was going to consider the intake into the medical schools in relation to future requirements. They had never in the Council made any inquiry into that problem, and there was a certain anxiety about it. He thought the time had come for such an inquiry, particularly in view of the fact that the Working Party was now proceeding to investigate, among other things, the way in which the young man could go into practice. He thought it would be sufficient, however, at this stage to instruct the office to obtain information which could be laid before the Council at an early meeting, when perhaps a subcommittee might be set up.

Dr. DAIN said that he had raised the matter in the General Medical Council, where it had been urged that the schools should look again at their intake, and that now, nearly seven years after the end of the war, they might safely go back to their optimum number. Dr. ROWLAND HILL suggested that the Ministry of Health might be asked for its views on the matter. Dr. F. M. ROSE said that it would be well to consider the intake in the schools outside the United Kingdom, notably in the Republic of Ireland and to some extent on the Continent.

It was agreed to ask the Secretary to look into this matter at an early date and collect information.

The Harvey Memorial

The Council further considered a report from the president of the Harveian Society concerning the condition of the Harvey sarcophagus and statue at Hempstead Church, Essex.

It was agreed that the Association should give any help in its power towards the preservation of this memorial.

Remuneration of Civil Service M.O.s

The recommendations of the Howitt Committee on the pay and organization of Civil Service medical staffs were placed before the Council. (These were the subject of an annotation in the *British Medical Journal* of November 17, 1951, p. 1206.)

The SECRETARY said that the Joint Committee (on which the Council was represented by Dr. Dain and Dr. Metcalfe Brown) thought that doctors entering the Civil Service should be selected just as carefully as entrants to the Administrative Class and should have just as attractive career prospects, and that their salaries should be brought into line with the remuneration obtaining in other branches of the profession. In April, 1950, the Council approved a claim which at the request of the Joint Committee was submitted to the then Chancellor of the Exchequer, who appointed the Howitt Committee to look into the problem. A comparison between the recommendations of the Howitt Committee and the claim originally put forward was a little complicated, but he entered into details which showed that the offer of the

Howitt Committee was considerably less than what had been claimed. A deputation to the Financial Secretary of the Treasury (Mr. Boyd-Carpenter, M.P.) was received on January 3, when the matter was presented on behalf of the profession in no uncertain terms. The Financial Secretary promised to transmit the views of the deputation to the Chancellor.

It was agreed that a letter be sent on behalf of the Council intimating to the Treasury that it fully supported the representations made by the deputation. Dr. R. P. LIPSON suggested, and it was agreed, that the point should be made in the letter that for some years now the Government had found it extremely difficult to recruit medical men to the Civil Service owing to questions of status—for example, the taking over of medical duties by lay administrators.

The SECRETARY added that although the committee which had been pressing the claims of these doctors was a joint one, and included the Institution of Professional Civil Servants and the Ministry of Health Medical Staff Association, the British Medical Association had played a very active part in these negotiations through the representatives appointed by the Council and through the Deputy Secretary (Dr. D. P. Stevenson), who had done a great deal of hard work.

The Amendment of the Acts

The Council then turned to consider the procedure to be adopted to further the decisions of the Representative Body on the reform of the National Health Service. The decisions were set out in the *Supplement* of January 5.

Dr. H. H. D. SUTHERLAND, chairman of the Amending Acts Committee, likened himself and his committee to wood-gatherers who had collected a large number of faggots, pulling them through difficult hedges and other obstacles. A large amount of material had been accumulated, and he thought it a matter of urgency, even though the work of the Committee was far from finished, that it should be presented to the Government forthwith by a strong deputation led by the Chairman of Council and the Chairman of the Representative Body, and including the Presidents (or their nominees) of the Royal Colleges. No opportunity should be given to the Minister to play off one section of the profession against another, nor must there be any suspicion that any section was trying to gain an advantage at the expense of another. It was true that there were a number of gaps in what they had to present; this could not be helped.

Dr. ROWLAND HILL pointed out that the major part of the report approved by the Special Representative Meeting consisted of matters affecting consultants and hospitals. Much of this material was already approved by the Royal Colleges as well as by themselves. It was important in this matter to have a common front with the Royal Colleges, and the way to do this, in his view, was to approach Dr. Russell Brain, the chairman of the Joint Committee, as representing the consultant side of the profession.

Dr. F. M. ROSE asked whether it was desirable to make such an approach as Dr. Sutherland had indicated before the matter, at any rate on the general-practitioner side, had been completed. General practitioners were very much concerned with their position in respect of the regional boards and with the question of access to hospitals. It might be better to leave the matter until they had a more complete picture.

Mr. S. F. L. DAHNE was quite certain that those who represented the common front would have the case of the general practitioner very prominently in mind. He did not think they ought to wait unduly. It might be months or a year or more before these other matters were worked out, whereas they had now certain concrete suggestions to present.

Dr. WAND pointed out that the arbitration machinery approved by the Representative Body had already been sent to the Ministry of Labour as a first step. On the common front they had the main picture, but if they were able to persuade the Minister of the necessity for carrying out certain alterations there would inevitably be a second

phase of detailed discussion, which would be carried on "at the selected level." It would be for the overall body on the common front to watch the developing situation and see that no section of the profession benefited at the expense of any other.

Dr. FRANK GRAY said that one important question had been overlooked. The administrative structure on the hospital side had now been based on hospital management committees, but the detailed composition of such committees had not yet been agreed. Were representatives of the profession to go to the Ministry and discuss with them the composition of management committees before the Representative Body had had an opportunity of discussion?

Dr. ROWLAND HILL emphasized that there had been no independent approach by the Royal Colleges to the Ministry.

Dr. DAIN pointed out that a great many of the proposals could be brought about without an amending Act. The Minister, when approached by the deputation, might be offered a draft of an amending Bill, but there were a number of anomalies which could be put right before such a Bill proceeded.

Dr. G. W. IRELAND said that they talked of a common front, but a common policy was more important. A very important section of the profession—the general-practitioner section—had not defined its policy. The General Practice Review Committee had not yet reported, and on its report would depend very largely what happened to general practitioners and, to some extent, to consultants and hospitals.

Dr. SUTHERLAND reminded the last speaker that at the Special Representative Meeting the Lothians motion for postponement was lost. The recommendations which the Amending Acts Committee had made were not interim, they were basic. They were the items which went to make up the foundation, and all the other details would follow in due course. With regard to hospital management committees, they had made proposals for the medical representation, but it was not their business to say how the lay element should be constituted.

Dr. O. C. CARTER asked whether the Government itself had got a draft amending Bill.

Lord HORDER said that he could not answer Dr. Carter's question from personal knowledge, but a very interesting answer was given in the House of Commons by the Minister of Health, from which it would appear that certain definite views expressed before the election had been put into cold storage. There was no intention on the part of the Government apparently to move in the matter of payment for medicines prescribed for private patients.

Dr. A. C. E. BREACH and Mr. DAHNE spoke of the dangers of delay.

After certain propositions had been moved by Dr. A. BROWN and Mr. DAHNE, the CHAIRMAN asked whether the Council could not agree to the following general line of action: that they should seek at the earliest possible moment to have a meeting with the chairman of the Joint Committee, at which the chairmen of the General Medical Services, Consultants and Specialists, Public Health, and Amending Acts Committees would be present, with the object of determining the best way in which their duty to the Special Representative Meeting could be discharged and its resolutions furthered, and that the results of the discussion should be reported to the Council at its next meeting; that in the meantime anything in the decisions which could go forward (as the section on arbitration machinery had already gone) should be pursued, and that a sense of immediacy should pervade all that was done in this connexion.

This course was agreed to.

Organization

On the report of the Organization Committee, presented by Dr. I. G. INNES, it was agreed that notice be given to dissolve the Indian Branches of the Association in view of the affiliation arrangements with the Indian Medical Association.

Certain proposals for consequential amendments to the articles and by-laws following the previous decision to extend membership of the Association to persons possessing a registrable qualification and who obtained provisional registration under the Medical Act, 1950, were referred back for clarification.

Another recommendation for the enlargement of the Public Relations Committee so as to include representation of other central committees was agreed to.

Dr. INNES drew attention to the increased membership of the Association. The membership on December 12, 1950, was 64,206, and on the corresponding date in 1951 it was 66,075.

Annual Meeting Arrangements

Proposals were brought forward for the amendment of the constitution of the Arrangements Committee, following, with a slight modification, the constitution of the committee appointed for the 1952 Annual Meeting in Dublin. These were referred back, however, for reconsideration of one point—namely, the representation from the area in which the Annual Meeting was held.

The Organization Committee had also drawn up a list of 11 towns, all of them health resorts with the exception of Edinburgh and Glasgow, suggested for inclusion among those at which Annual Meetings should be held on a rotation basis.

Dr. DAIN said that he was grieved to see a proposal that they should desert university centres for health resorts. He thought that, despite the increased size of the Annual Meeting, Birmingham and probably other university centres could accommodate it.

This proposal also was referred back.

It was reported that Mr. Lawrence Abel (who was unfortunately unable to attend the Council meeting owing to illness) had visited Dublin to ascertain the possibility of organizing on a small and experimental scale a scientific exhibition in connexion with the Annual Meeting there in July next. He had come to the conclusion that this could be done and that it would form a useful and interesting feature of the meeting. What was in mind was from 24 to 36 booths at University College for exhibits of clinical and pathological material, contributed by the hospitals of the Irish Republic and of the United Kingdom.

The Council approved the proposal. The CHAIRMAN said how greatly they were indebted to Mr. Abel for his enterprise in this respect. The PRESIDENT-ELECT also spoke in complimentary terms of Mr. Abel's zeal and enthusiasm. The Council sent him a message wishing him a swift recovery from his illness.

It was reported that a difficulty had arisen over the arrangements for the Annual Meeting, 1953, at Llandudno, owing to the fact that the building in which it was proposed to house the trade exhibition had become unavailable, and there was no other suitable place for this purpose.

It was agreed to hold the matter over until the next meeting of Council, when a firm decision must be made on whether the arrangements should proceed. It was felt that it would be a great pity if the meeting could not be held in Wales, because in 1953 it would be exactly 50 years since the first Representative Meeting was held in the Principality (at Swansea).

An invitation was reported from the Brighton Division to hold the Annual Meeting at Brighton in 1954. It was decided to defer consideration of this until the next meeting.

The British Medical Journal

It was agreed that the students' subscription rate to the *British Medical Journal* should be increased from 10s. 6d. to £1 1s. per annum.

Dr. O. C. CARTER, chairman of the Journal Committee, spoke again of the great increase in paper and production costs. The question of possible economies had exercised the Committee considerably. In view of the financial situation it was proposed to reduce the number of literary pages

by 208 (an average of four pages a week) in 1952 as compared with the number printed in 1951. He added that last year the *Journal* carried more advertisements than previously. It was the increasing costs which had led to the present position.

The suggestion was made in the Council that the number of pages be cut by eight a week instead of four, but several members spoke against this further cut, Mr. H. H. LANGSTON pointing out that there were many sections and interests in the profession to which the *Journal* appealed.

Lord HORDER said that, having recently become a member of the Journal Committee, he had been impressed by the thoroughness with which the Committee carried out its labours. The prestige of the *Journal* was very high alike with the medical profession and the general public. Any form of cut was a misfortune in itself, but it might have to be accepted. A cut more extensive than the one proposed, however, would mean risks and dangers, some of which had not been explored by the Journal Committee.

It was agreed that the question of any further cut beyond the four pages be remitted to the Committee for consideration.

Dr. CARTER also referred to the recommendations made by the Winchester Divisions for the improvement of the *Supplement*. The *Supplement* had been criticized on the ground that it did not publish sufficient up-to-date information on medico-political matters, and also on the ground that its contents were unattractively presented, very much in the style of an official gazette. On the first point it had to be borne in mind that much of the business before the Council and its committees was confidential. As for the supposed dullness of the *Supplement*, the Association was compelled by its by-laws to insert a large number of official communications which were bound in the nature of the case to be dull reading. But no effort was being spared to improve the *Supplement*, and he presented to the Council a long memorandum by the Editor on the subject.

Mr. NICHOLSON-LAILEY said that, after all, what they chiefly required of the *Supplement* was that its information should be accurate and succinct, and that requirement was fulfilled. Dr. ROWLAND HILL suggested that the chairmen of committees might be asked from time to time to write a statement, and they could be "discreetly indiscreet" and take responsibilities which the secretaries might not be prepared to assume. Dr. DAIN said that the *Supplement* might be presented more journalistically.

On the motion of Dr. R. GIBSON, seconded by Mr. LANGSTON, it was agreed that the Journal Committee should consider the recasting of the *Supplement* and bring forward a report as a matter of urgency at the next meeting of Council.

Dr. CARTER also presented a report from the Family Doctor Committee dealing with such matters as typography and lay-out and the promotion of circulation.

Association Finance

The TREASURER (Mr. A. M. A. Moore) presented a report of the Finance Inquiry Committee, embodying suggestions by the Secretary for the curtailment of certain activities which would lead to economy in running the Association. On a recommendation from this committee the Council decided to invite one of the leading firms of management consultants—Harold Whitehead and Partners—to survey the organization and clerical methods of the Association, to ensure that its affairs are conducted with the utmost efficiency and economy.

The Council agreed to set up an *ad hoc* committee consisting of the Officers, O. C. Carter, L. Dougal Callander, and H. Guy Dain, with the Secretary, the Editor, and the Finance and Business Officer, to consider and if necessary to put into practice the recommendations made from time to time by the investigators and to authorize progressive extensions of the inquiry.

Among various economies agreed to was the discontinuance of the practice of paying an honorarium of 10 guineas

to B.M.A. lecturers, also of the practice of paying travelling expenses to London of the parties to ethical disputes and of their witnesses. Other economies took the form of the replacement of printed by stencilled documents and the limitation of meetings of committees and conferences.

Dr. J. G. M. HAMILTON moved that payment of third-class fares be substituted for first-class in the case of members attending Representative and Council meetings and committees and subcommittees, and this was seconded by Dr. G. W. IRELAND, but was not carried, and a further motion from the same members, that members of the staff in receipt of remuneration of £1,500 per annum and over should be asked to accept a temporary cut of 5%, on the understanding that this would be the first of the cuts to be restored, found support only from the proposer and seconder.

Public Health

Dr. C. METCALFE BROWN, chairman of the Public Health Committee, gave an account of the proceedings of a conference which had taken place the previous day between representatives of the Ministry of Health, the local authorities' associations, and the British Medical Association on remuneration and other matters connected with "dual appointments" (see p. 42). After some discussion it was decided to refer this matter, which was edged with some difficulty, to the appropriate committees of the Association, the Society of Medical Officers of Health, and the Joint Consultants Committee. So far as any decision of the Council might be required, the question was left open until the next meeting.

Other matters in the Public Health Committee's report were covered in the account given of its proceedings in the *Supplement* of December 29, 1951.

The Adjudication

Dr. WAND presented a report from the General Medical Services Committee. Most of the matters contained therein have been covered in the reports in the *Supplement* of the two meetings of the Committee which have taken place since the last Council meeting. Dr. Wand stated the position with regard to the forthcoming adjudication, and in reply to Dr. Vaughan Jones and Dr. Angus Weston, who said that some members in their localities were becoming restive over the prolonged delay, pointed out the complicated issues involved and the necessity for counsel to be most fully instructed. He deprecated ill-informed letters in the *Journal*. It was not realized by many members what large questions were being opened up, concerning rates of income, practice expenses, remuneration received by other professions, and so on. A meeting between Mr. Justice Danckwerts and counsel on both sides was arranged for January 30. [A leading article on the preparation for adjudication appears at p. 263 of the *Journal*.]

A report of the Compensation and Superannuation Committee was also presented by Dr. WAND. The Ministry had announced that the rate at which compensation would be payable, expressed in years' purchase, would be 1.5847. All doctors entitled to compensation had been notified of their assessments, and the Ministry would inform each doctor as soon as possible of the exact sum which would be eventually payable to him. In notifying practitioners of the amount of their compensation, priority would be given to those doctors who had retired and the representatives of those who had died. He thought that having regard to all the circumstances they had not done so very badly.

Consultants and Specialists

The Council agreed, on the proposition of Dr. ROWLAND HILL as chairman of the Consultants and Specialists Committee, that the position of practitioners in whole-time salaried appointments in relation to income tax should be examined with a view to the submission of evidence to the Royal Commission on Income Tax.

An amendment in the constitution of the Anaesthetists Group Committee was agreed to.

One section of the report of the Consultants and Specialists Committee was on the desirability of a uniform practice in dealing with accidents or incidents in hospital which might lead to a complaint being made involving members of the medical staff. It was suggested that there should be a standardized form of accident report which would not be compulsorily disclosable in the event of a legal action or voluntarily disclosed by the hospital in court or to any third party without the practitioner's consent. Dr. Gorsky suggested that this might cut across the legal requirement for discovery of documents. Any document could be required to be disclosed if it was prepared before legal action was contemplated.

Scottish Committee

A recommendation from the Scottish Committee that the reconstruction of the Scottish House, Edinburgh, so far as it calls for the expenditure of Association money, should be deferred pending the report of the Finance Inquiry Committee was agreed to. The Council expressed its appreciation of this valuable Scottish contribution.

Dr. VAUGHAN JONES drew attention to an item in the Scottish Committee's report concerning payments to practitioners for attendance in emergency at mining accidents. He said that apparently negotiations had been going on in Scotland which affected the whole country, but the Occupational Health Committee, of which he was chairman, had known nothing about them. Dr. GRANT, chairman of the Scottish Committee, said that they had been reported to the General Medical Services Committee.

An undertaking was given that in future any matters of this kind would also be reported before their conclusion to the Occupational Health Committee.

Other Committee Reports

Dr. VAUGHAN JONES presented the report of the Occupational Health Committee, the proceedings of which were reported in the *Supplement* of January 19. A recommendation concerning the reference of occupational dermatitis cases and another concerning the procedure for claiming benefit in respect of pneumoconiosis were agreed to.

A report of the Amending Acts Committee containing a list of the subjects on which it is proposed to present a second interim report to the next meeting of Council was made by Dr. SUTHERLAND and approved.

Dr. GRANT presented a report of the Private Practice Committee which was approved save for one item, concerning Ministry of Labour Medical Boards, which was referred back for further consideration.

A report of the committee appointed by the Council to prepare evidence for submission to the Royal Commission on Marriage and Divorce was presented by Dr. Dain. He said that he thought the Council would agree that the changes suggested in the memorandum of evidence were dictated by common sense. The memorandum was approved.

Dr. J. G. THWAITES submitted a memorandum of evidence, prepared by a special subcommittee, for submission to the Ministry of Education Committee on Maladjusted Children. The memorandum was approved, and Dr. Doris Odium, chairman of the subcommittee, Dr. Thwaites, Professor D. R. MacCalman, and Dr. A. A. E. Newth were appointed to give oral evidence in support.

Dr. THWAITES also presented a report from the Central Ethical Committee. It dealt only with routine matters and contained no recommendations. It was stated that the Committee was seeking the opinion of the General Medical Council on the general question of the conversion of medical practices into companies. Dr. BREACH expressed some dubiety regarding the formation of limited liability companies by medical practitioners.

Major-General Dowse, for the Colonies and Dependencies Committee (henceforth to be called the Overseas Committee),

said that the Committee proposed to address a communication to the Branches in the Colonies setting out the principles which it considered should so far as possible be followed in the undertaking of private practice by Government medical officers.

Major-General DOWSE also reported for the Armed Forces Committee. He said that the Committee was making further representations concerning the pay of reserve officers upon mobilization.

Routine reports were submitted by the Public Relations, Building, Office, and Staffing Committees.

Arbitration Machinery

The SECRETARY said that the committee sitting under the chairmanship of Dr. Gregg, the Chairman of Council, had instructed him to make a further approach to the Minister of Labour through Sir Robert Gould, Chief Industrial Commissioner, drawing attention to the resolutions passed by the Representative Body defining the character of the arbitration machinery which it was desired to establish and asking for his assistance in securing an arbitration agreement which would form an apex to the existing collective bargaining procedure. Sir Robert Gould had replied that he himself could not make any further suggestions unless the matter was discussed jointly with the Association and the Ministry of Health. To this he had replied that he hoped it would be possible for Sir Robert Gould at an early date to arrange a meeting at which representatives of both Ministries would be present. Sir Robert Gould had written to the Ministry of Health, and its reply was now awaited. The Council had decided that unless substantial progress were made in this matter during the month of January it would ask the Ministry of Labour to amend the Industrial Disputes Order in such a way as to exclude the medical profession entirely from the operation of the Order.

The Council agreed that if within a week no further communication were received the Secretary should again write to Sir Robert Gould pressing very strongly for this meeting with the two Ministries concerned.

BRITISH MEDICAL GUILD

On the day of the Council meeting a meeting of the Board of Trustees of the British Medical Guild was held under the chairmanship of Dr. E. A. GREGG, when reports were received from the Public Health Service Defence Trust and the Hospital Medical Staffs Defence Trust, also a statement from the Finance and Business Officer on the finances of the Guild Trust Fund.

CONTROL OF MEDICAL MANPOWER IN PEACE AND WAR

The following scheme has been agreed by the profession and the Government, but Appendix F (Part A) is subject to review after one year, and the Council of the B.M.A. has approved the scheme on condition that the same arrangement apply to Appendix H.

Ministerial Responsibility

The responsibility for policy in the control of medical manpower will rest upon a committee of the Cabinet. The implementation of policy will be entrusted to the Minister of Health and the Secretary of State for Scotland, who will act in consultation with other Ministers concerned.

Advisory and Executive Machinery

(a) A National Medical Manpower Committee corresponding to the present Medical Priority Committee will be appointed in consultation with the medical profession to keep under constant review the best methods of utilizing the available medical manpower and to make recom-

mendations to the Government from time to time. The Committee will cover Scotland as well as England and Wales. Its constitution is shown in Appendix A below.

(b) *Two Central Recruitment Committees* corresponding to the present Central Medical War Committees will be appointed, one for England and Wales and one for Scotland. Members will be independently appointed by the organizations concerned in accordance with the constitutions shown in Appendices B and C below.

(c) *Area Recruitment Committees* will be appointed to assist the Central Recruitment Committees in connexion with

- (i) the recruitment of individual doctors to H.M. Forces;
- (ii) the "screening" of doctors with reserve commitments who are earmarked for recall in the event of war;
- (iii) the "screening" of doctors volunteering for the Reserve and Auxiliary Forces, including the Territorial Army.

Separate committees will be formed to deal with general practitioners, hospital and university officers, and public health officers. The constitution of these committees is shown in Appendices D to I below. Medical practitioners working in other than the three main forces mentioned above will be dealt with by the appropriate Central Recruitment Committee.

Register of Profession

To assist all committees, a comprehensive register of the profession will be compiled from questionnaires issued to all members of the profession for completion on a voluntary basis. The Register will be kept by the B.M.A., the Central Committees and other agencies concerned having full access to it. It is hoped that the Register, brought up to date and amplified as necessary, will satisfy the requirements of any general compulsory registration of medical practitioners which might be instituted in the event of war.

Procedure

The procedure for recruitment to H.M. Forces, which will operate both in peace and in war, is shown in Appendix J below.

The procedure for the "screening" of doctors with Reserve commitments who are earmarked for recall in the event of war and of doctors volunteering for the Reserve and Auxiliary Forces, including the Territorial Army, is shown in Appendix K below.

The procedure for the allocation of individual doctors to satisfy wartime civilian needs at home will be the subject of further consultation with the profession.

APPENDIX A: THE NATIONAL MEDICAL MANPOWER COMMITTEE

Constitution

The National Medical Manpower Committee will consist of 10 members (including two to represent Scottish interests) appointed by Ministers as individuals with special knowledge and experience of consultants and general practice, medical schools, medical research and public health, selected in consultation with the Presidents of the Royal Colleges and of the Royal Scottish Corporations, the Medical Research Council, the British Medical Association, the Medical Women's Federation, and the Society of Medical Officers of Health.

The chairman will be appointed by Ministers after consultation with the profession. All members of the committee will be registered medical practitioners. The term of office of members will be three years. One-third of the members will retire each year in rotation and be eligible for reappointment.

Representatives of the Health and Service Departments, the Ministry of Labour and National Service, the Government of Northern Ireland, and of each Central Recruitment Committee will attend meetings as advisers.

APPENDIX B: CENTRAL RECRUITMENT COMMITTEE—ENGLAND AND WALES

Constitution

The Committee will be constituted as follows:

<i>Appointed by</i>	<i>No. of Members</i>
The Royal College of Physicians	3
The Royal College of Surgeons	3
The Royal College of Obstetricians and Gynaecologists	2
Specialist associations in consultation with the corresponding specialist Group Committees of the British Medical Association, viz.: anaesthetists, ophthalmologists, otorhinolaryngologists, pathologists, psychiatrists, radiologists, venereologists	7
The Society of Medical Officers of Health	1
The Medical Women's Federation	1
The Parliamentary Medical Committee	1
The British Medical Association	27
	45

The committee will be appointed annually. It will appoint its own chairman and any necessary subcommittees.

Representatives of the Health and Service Departments, the Ministry of Labour, and the Medical Research Council will attend the meetings as advisers. Representatives of other Government departments, including the Ministry of Supply, will be invited to attend when business concerning them is under consideration.

APPENDIX C: CENTRAL RECRUITMENT COMMITTEE (SCOTLAND)

Constitution

The Committee will be constituted as follows:

<i>Appointed by</i>	<i>No. of Members</i>
General Medical Services Subcommittee (Scotland) of the B.M.A.	4
Joint Committee for Consultants and Specialists (Scotland), including one representative each from the Royal College of Physicians, Edinburgh; the Royal College of Surgeons, Edinburgh, and the Royal Faculty of Physicians and Surgeons, Glasgow	4
Scottish Branch of Society of Medical Officers of Health	2
Scottish Executive Council's Association	2
Chairman's Committee of Regional Hospital Boards	1
Local Authority Associations	1
Deans of the medical faculties of the four universities	1
	15

The committee will be appointed annually. It will appoint its own chairman and any necessary subcommittees.

Representatives of the Service departments, the Department of Health, the Medical Research Council, and the Ministry of Labour will attend meetings as advisers. Representatives of other Government departments, including the Ministry of Supply, will be invited to attend when business concerning them is under consideration.

APPENDIX D: AREA COMMITTEES FOR GENERAL PRACTITIONERS (ENGLAND AND WALES)

Constitution for Each Executive Council Area

The Area Committee for each executive council area will consist of members appointed annually by the local medical committee together with one lay member appointed by the executive council.

The size of the committee will be at the discretion of the local medical committee, and the Area Committees will have power to co-opt.

It will be for the local medical committee to ensure that general practitioners not in the National Health Service are appropriately represented on the Area Committee.

APPENDIX E: AREA COMMITTEE FOR GENERAL PRACTITIONERS (SCOTLAND)**Constitution for Each Executive Council Area**

The Area Committee for each executive council area will consist of members appointed annually by the local medical committee together with one lay member appointed by the executive council.

The size of the committee will be at the discretion of the local medical committee and the Area Committees will have power to co-opt.

It will be for the local medical committee to ensure that general practitioners not in the National Health Service are appropriately represented on the Area Committee.

APPENDIX F: AREA COMMITTEES FOR HOSPITAL AND UNIVERSITY OFFICERS (ENGLAND AND WALES)**Constitution****A. LONDON AREA (to cover the four Metropolitan Regional Hospital Board areas):**

The Senior Administrative Medical Officer of each Regional Hospital Board	4
Appointed by:	
Regional Consultants and Specialists Committees (2 from each R.H.B. Area)	8
The Royal College of Physicians	2
The Royal College of Surgeons	2
The Royal College of Obstetricians and Gynaecologists	1
The Dean of the Faculty of Medicine, London University	1

18

The committee will be appointed annually. It will appoint its own chairman and will be free to delegate the work to subcommittees, on a geographical or functional basis, as may be necessary.

B. PROVINCES for each Regional Hospital Board Area:

The committee will be wholly professional and will be set up by the Regional Consultants and Specialists Committee in accordance with the following constitution:

The Senior Administrative Medical Officer of the Regional Hospital Board	1
Appointed by:	
The Regional Hospital Board	1
The Board of Governors of the Teaching Hospital	1
The University	1
The Regional Consultants and Specialists Committee	8

12

The committee will be appointed annually and will appoint its own chairman.

A medical officer of the Ministry of Health will be associated with each committee as adviser.

APPENDIX G: AREA COMMITTEES FOR HOSPITAL AND UNIVERSITY OFFICERS (SCOTLAND)**Constitution for Each Regional Hospital Board Area**

The committee will be set up by the Regional Consultants and Specialists Committee in accordance with the following constitution:

The Dean of the Medical Faculty in the appropriate university or his nominee	1
The Senior Administrative Medical Officer of the Regional Hospital Board or his nominee	1
Appointed by the Regional Hospital Board (one at least being a medical practitioner)	2
Appointed by the Regional Consultants and Specialists Committee	8*

12*

*Subject to minor variations from region to region.

The committee will be appointed annually and will appoint its own chairman.

A medical officer of the Department of Health for Scotland will be associated with each committee as adviser.

APPENDIX H: AREA COMMITTEES FOR PUBLIC HEALTH MEDICAL OFFICERS (ENGLAND AND WALES)**Constitution for Each Civil Defence Region**

- 2 medical practitioners representing County Council areas
- 3 medical practitioners representing County Borough and non-County Borough areas
- 1 medical practitioner representing Urban and Rural District Council areas

Standing Deputies will be appointed.

Notes.—(1) Three members to be appointed by the Society of Medical Officers of Health, and three by the association of local authorities, after consultation between all the bodies concerned (special arrangements will be necessary for the London area). (2) Each committee will be appointed annually and appoint its own chairman. (3) A medical officer of the Ministry of Health will attend each committee as adviser.

APPENDIX I: AREA COMMITTEE FOR PUBLIC HEALTH MEDICAL OFFICERS (SCOTLAND)**Constitution**

One committee will cover the whole of Scotland and will be constituted as follows:

Appointed by the Local Authorities Associations	1
Appointed by the Scottish Branch of the Society of Medical Officers of Health	7
	8

The committee will be appointed annually and will appoint its own chairman. A medical officer of the Department of Health for Scotland will be associated with the committee as adviser.

APPENDIX J: PROCEDURE FOR RECRUITMENT TO H.M. FORCES

(a) The estimated requirements formulated by the fighting services will be examined by the National Medical Manpower Committee, which will advise on the extent to which they can be met and on the quota to be provided from England and Wales and from Scotland.

(b) The central recruitment committees for England and Wales and Scotland will determine the categories and the quota of practitioners to be recruited from each regional hospital board area, executive council area, and the public health service. They will have access to the register of all doctors to be maintained by the B.M.A.

(c) Nominations of doctors in the three main fields—viz., hospital and university officers, public health medical officers, and general practitioners—will be made by the appropriate area committees.

(d) Where a doctor under review is engaged in more than one of the three main fields—as, for example, a general practitioner in contract with a regional hospital board as well as an executive council—the question of his recruitment will be determined by the area committee dealing with his predominant employment after consultation with any other area committee concerned.

(e) Practitioners working wholly or partly outside the three main fields—for example, an industrial medical officer employed by a firm on clinical work, a research worker, or a practitioner in the Public Health Laboratory Service—will be dealt with by the Central Recruitment Committee after inquiry in the appropriate quarter.

APPENDIX K: "SCREENING" OF DOCTORS

Procedure for the "Screening" of Doctors with Reserve Commitments who are Earmarked for Recall in the Event of War and Doctors Volunteering for the Reserve and Auxiliary Forces, including the Territorial Army

Lists of doctors with reserve obligations—for example, Regular Reservists, Territorials, Class Z, and similar reservists—will be furnished by the Service departments to the Central Recruitment Committees. Certain categories of these reservists will be indicated in the lists by means of an asterisk (or by other suitable means) as *prima facie* available for immediate recall.

The Central Recruitment Committees, after securing the advice of the appropriate Area Committees, will classify these doctors as "available" or "not available" for immediate recall; but a doctor whose name is marked with an asterisk may be classified "not available" with the consent of the Service departments concerned.

The Central Recruitment Committees will classify doctors volunteering for the Reserve and Auxiliary Forces (including the Territorial Army) as "available" or "not available" for immediate embodiment in the event of war.

GENERAL PRACTITIONERS' REMUNERATION

PREPARING THE CASE

A leading article in the *Journal* at page 263 describes and comments on the preparation of the general practitioners' case for higher remuneration. As announced last week, counsel of both sides met the adjudicator, Mr. Justice Danckwerts, on January 30 to discuss the procedure for the hearing.

PUBLIC HEALTH SERVICE

IMPLEMENTATION OF THE AWARDS

At a meeting of the Whitley Committee C on January 22 a number of points in connexion with the awards were discussed. Certain items were agreed, and decisions will be issued by the joint secretaries in M.D.C. circulars in the near future. At a preliminary meeting of the staff side of Committee C a full report of the acceptance and implementation of the Industrial Court awards was given.

The figures as at January 21 are as follows:

As regards the overall position in England, Scotland, and Wales, of local health authorities and local authorities 73% have accepted and implemented the first award and 70% the second award. Of local health authorities in England, Scotland, and Wales 85% have accepted and implemented the first award and 83% the second award. The breakdown of the last two figures is as follows:

	1st Award	2nd Award
Counties	93%	91%
County boroughs	75%	80%
Counties of cities	75%	100%

The secretary reported that the position was improving daily as information was received from local authorities accepting the award.

The staff side discussed the question of the present remuneration of the junior categories in the public health service and is undertaking a review of the position.

DUAL APPOINTMENTS

A conference was held on January 22 between representatives of the British Medical Association, the associations of local authorities, and the Ministry of Health regarding dual appointments. After long and detailed discussion some progress was made towards agreement, but certain outstanding points are still the subject of consideration. It is hoped that these points will be clarified in the near future, and a further meeting has been arranged for March 10.

MILEAGE ALLOWANCES FOR HOSPITAL MEDICAL STAFF

New mileage rates for hospital doctors are expected soon.

During recent months a great deal of dissatisfaction has been expressed by members of hospital medical staffs at the inadequacy of the mileage allowances laid down in the Terms and Conditions of Service. Indeed, they were not accepted by the profession as adequate in 1949, when the Terms of Service were introduced, and strenuous efforts were then made to secure more satisfactory allowances, but without success. Since that time the costs of petrol, oil, tyres, insurance, and repairs have all risen, with the result that the payments made by hospital authorities nowhere meet the expenses incurred by hospital medical staffs using their cars in the performance of their duties.

The matter was raised by the staff side of Whitley Committee B, early in 1950, but the view of the management side was that, as the mileage rates payable to medical staff were applicable generally to all types of hospital staff, the question was one for the General Whitley Council. More recently the staff and management sides of the General Whitley Council have been considering various proposals for improving the existing mileage rates, following the adoption of new scales for public health medical officers and members of hospital boards and committees. As a result new mileage rates for hospital staff generally are likely to be announced shortly.

MEDICAL SUPERINTENDENTS

AWARD OF INDUSTRIAL COURT

Ever since the appointed day the B.M.A. has been trying to improve the position of medical superintendents. Discussions were held originally direct with the Ministry of Health and latterly through Whitley machinery. No satisfaction was obtained, and therefore the case was submitted to arbitration by the Industrial Court. On January 22 the Court gave its award on the claim. It refers to medical superintendents in England and Wales, and is as follows:

1. A medical superintendent graded as consultant or S.H.M.O. and normally engaged in clinical work for 32 hours a week shall be paid wholly in accordance with the appropriate clinical scale. (Consultants receive £1,700 to £2,750 plus merit awards and S.H.M.O.s £1,300 to £1,750.)

2. The salary for medical superintendents wholly engaged on administrative duties shall be £1,350 to £1,750. The scale appropriate in particular categories of hospitals is to be determined by agreement or, if that fails within two months, by the Court.

3. Medical superintendents whose duties are partly clinical and partly administrative, and who are doing less than 32 hours' clinical work a week, shall have their salaries apportioned as follows: on the clinical scale for that part of their time spent on clinical work, and on the medical superintendents' scale in (2) above for that part of their time spent on administrative work. (In this connexion a medical superintendent's working week is deemed to be 38½ hours.)

4. Medical superintendents at present in post shall enter the revised salary scales at the point they would have reached if the scales had been in operation on the date of appointment to their present post or on July 5, 1948, whichever is the later.

5. The revised scales shall be implemented retrospectively to October 1, 1950.

6. No salary is to be reduced by the award.

Award Falls Short of Claim

This award will be disappointing to medical superintendents, since it falls considerably short of their claim. For wholly administrative work they were asking that the

salary scale should be within the minimum and maximum limits of £1,700 and £2,550, according to the type of hospital and duties involved. The award is much below those figures. They also asked that the new salary scales should be retrospective to July 5, 1948, whereas these have been made retrospective to a date over two years later.

There are 380 medical superintendents in England and Wales. According to evidence submitted by the management side, three of these are wholly on clinical duties and eight wholly on administrative duties, the remaining 369 doing both kinds of duties. Of the 369, all but 20 are said to be receiving the full clinical salary. Of these 20, only five are being paid by the fractional method of apportioning salaries, the other 15 having elected to continue on the same basis as before the appointed day. All the eight medical superintendents engaged wholly on administrative duties had elected to retain their pre-appointed-day salaries and not one was on the lay administrative rate.

Though medical superintendents will be disappointed with this award, there are two features of it which give some cause for satisfaction. The first is that the 369 medical superintendents doing both clinical and administrative duties have had their remuneration safeguarded from possible—and indeed expected—cuts imposed by the Ministry of Health. The second is that the award for the whole-time administrators, though unsatisfactory, is better than the offer made by the management side.

APPLICATION TO TRIBUNAL URGED

The London Executive Council has recommended to the Ministry of Health that £1,000 be withheld from a doctor's remuneration. According to the report of the medical services committee, the doctor was a principal in general practice on the list of the executive council and had since August, 1949, been employed as a full-time medical officer at a hospital about 12 miles away from his surgery premises. Throughout this time his list of N.H.S. patients was over 2,000.

The report also states that the doctor claimed and received about £777 from the executive council in respect of training a trainee assistant from November, 1949, to October, 1950, and that since October, 1950, he had employed a full-time assistant without the executive council's consent.

The executive council also decided to apply to the Tribunal for the exclusion of the doctor from the medical list and to seek the opinion of counsel about legal proceedings against him.

FEES FOR LECTURES TO NURSES

Following discussions in Whitley Committee B it has now been agreed between the staff and management sides that the fees payable to members of hospital medical staffs for lectures given to nurses should be as follows:

£2	2s. 0d.	per lecture for lectures by consultants
£1	11s. 6d.	" " " " " " S.H.M.O.s
£1	1s. 0d.	" " " " " " other grades of medical staff

These fees apply to lectures authorized to be given in any subject as part of the course of training, and they may be retained by whole-time or part-time officers.

It has also been agreed that no payment should be made to medical staff who undertake the written or oral examination of nurses in connexion with any internal examination instituted by the hospital.

In many hospitals the payment of fees for lectures to nurses has been held up for some time awaiting a decision in Whitley, and it is to be assumed that in these cases payment at the agreed rates will be made retrospectively.

PRESCRIBING AND THE PUBLIC

NORTHERN IRELAND NOTICE

The average cost of supplying medicine and appliances in Northern Ireland is much higher than in England—£1 0s. 4d. a head a year as compared with 15s. 6d. The Northern Ireland General Health Services Board takes a serious view of this (Third Annual Report for 1950-1).

It has therefore issued a notice to all Health Service doctors for the information of their patients. It is said to have been widely welcomed by doctors "as a means of bringing home to the more thoughtless or acquisitive of their patients the proper function of the practitioner as a prescriber rather than a mere supplier on demand of household and toilet requisites." A considerable reduction in the £1 0s. 4d. is said to be possible without in any way restricting the "proper and necessary treatment" provided under the Health Services Act.

Not on Demand

The notice says that the following practice will be observed by all Health Service doctors when prescribing.

"(1) Medicines or appliances selected by or on behalf of a patient will not be supplied when demanded or requested. The doctor will supply only those medicines and appliances which he decides are necessary for patients under his care.

"(2) Laxatives, vitamins, or 'tonics' will not be supplied for routine use, but only for the treatment of definite clinical conditions.

"(3) Malt and cod-liver oil will not be supplied except in cases of active tuberculosis or other organic disease.

"(4) Cotton-wool, lint, other dressings, and disinfectants will not be supplied for routine use in the sick-room nor for maternity cases. These materials will be supplied for use only by or for a patient under the doctor's care on account of an open lesion or for an acute inflammation."

Heard at Headquarters

Exchanges with French Children

There are several French doctors who would like to arrange holiday exchanges between their children and the children of doctors in this country. Anyone interested should write to Dr. Sandiford, International Medical Visitors Bureau, B.M.A. House, Tavistock Square, London, W.C.1.

Fifty Years in Bishopbriggs

Dr. J. B. Miller has recently completed half a century in general practice in Bishopbriggs. If there is any benighted Englishman who does not know where Bishopbriggs is, let it be said that it is on the Lanarkshire border in the valley of the Clyde, only 15 minutes' bus ride from Glasgow Cross, the centre of a mining and agricultural community, among whom Dr. Miller has found his life's work. But Dr. Miller has other records to his credit. When he resigned from the Public Health Committee of the Association in 1950 he had been a member of the committee for a quarter of a century. His election as chairman of the Representative Body took place on the very day that the late Labour Government came into office, and his term ended in the week that the National Health Service came into operation. During those three years he presided over seven Representative Meetings, and steered them, a perfect moderator, through a whole mass of contentious business. Probably few members of the Association have exercised so much influence as a result of so few words. In the chair he was never once "rattled," and if he rebuked any representatives it was done in so whimsical a manner that the lesson remained and not the sting.

Correspondence

False Economy

SIR,—I would like to draw attention to one example of false economizing in hospital expenditure whereby the Health Service may in fact cost more. A patient with severe dermatitis was admitted to an important general hospital where apparently not enough gauze was allowed to the ward, so bandages were applied direct to the affected parts. At the patient's request his wife brought such gauze as she had left over from home treatment, which was gratefully received by the nursing staff. Then the patient's wife came to me with the story (and I do not suspect she is trying to deceive me) and asked me to prescribe gauze on Form E.C.10 so that she could take it to hospital.

Clearly gauze bought retail, with the dispensing fee in addition, is much more expensive than wholesale supplies direct to the hospital—apart from all the extra trouble involved. However, this will doubtless show a book reduction in hospital expenditure and please some hospital bureaucrat. And meanwhile the G.P.s can be blamed for the rising cost of articles prescribed.—I am, etc.,

Brighton.

R. S. SEXTON.

Cost of Prescribing

SIR,—Mr. A. Daunt Bateman (*Supplement*, January 19, p. 23) states that manufacturers deliberately withhold mention of prices on their leaflets giving particulars of their preparations.

This is not a matter of "will not" but "cannot," as there is no fixed price for a prescription. The cost of an N.H.S. prescription for a proprietary medicine to the Ministry of Health is calculated on the initial cost of the material used by the chemist, which varies according to the quantity purchased, plus an agreed on-cost, a dispensing fee, and a charge for the container. These calculations are different in England, Scotland, and Northern Ireland, and are moreover subject to "averaging."

Our medical representatives have instructions to give particulars of our prices to any doctor who is interested. They carry a schedule showing the approximate dosage cost compared with that of any non-proprietary substitute that is suggested by the Ministry as a suitable less expensive alternative. The price difference is very small, and in some cases the non-proprietary is the more expensive. These prices can be only approximate and some explanation is necessary. A clear indication of the prices on a leaflet is not practical.—I am, etc.,

K. J. GOLDS,
William R. Warner and Co., Ltd.

Infection in Hospitals

SIR,—Dr. William Picton (*Supplement*, December 29, 1951, p. 292) protests too much. He is quite correct when he maintains that the control of infection within the ward is the responsibility of the clinician and the ward sister; and I share his doubts whether the ward sister's weekly returns to the matron will be worth the labour—unless, of course, they are used to maintain a series of epidemiological charts, which might be more useful in the office of the medical superintendent, the area medical officer, or the hospital hygiene officer. Nevertheless, there is a real need for a hygiene officer and for a control-of-infection committee in most hospitals.

One day Dr. Picton will realize that there are some infections which cannot be controlled by the individual clinician. Such are the enterica, which may become epidemic when one of the kitchen staff is infected. Presumably Dr. Picton would not have his clinical colleagues each instructing the kitchen staff and would leave this to the medical superintendent. Some hospitals have no medical superintendent,

and even where they exist they are not always experts in public health and hygiene and may need advice.

In at least one hospital the bacteriologist has been *ex officio* the sanitary or hygiene officer. As such, he advises the lay committee on the hygiene of the hospital, and his colleagues when some unusual outbreak of infection occurs. He is responsible for the design and performance of all investigations in an outbreak of infection, and in emergency may assume executive power.

Some years ago I saw the value of this system. Single cases of Sonne dysentery appeared in several wards; within a few hours of their recognition the hygiene officer and the medical superintendent were examining the kitchens. On the hygiene officer's advice considerable changes were made, and within a few days the outbreak ceased.

In such an event the hygiene officer may need executive or even dictatorial powers. He would be wise to exercise these through the medical superintendent or the chairman of the management committee, but in extreme urgency he may have to act on his own responsibility. Power over other departments of the hospital can be delegated only by a board of governors or a hospital management committee; and therefore a hygiene officer must be responsible to the delegating authority, whether lay or medical.

The control-of-infection committee seems to be admirably designed to translate the advice of the hygiene officer (which may be couched in general terms) into simple and practical rulings for any department of the hospital. I should prefer to add the kitchen superintendent to the committee, for all the more explosive outbreaks are initially ascribed to his department. Further, the hygiene of hospital kitchens often leaves much to be desired, for sometimes the simplest sanitary necessities, such as wash-basins near the W.C., are lacking. If the circular does no more than persuade hospital management committees to review their kitchen sanitation, it will have served its turn.

Finally, Dr. Picton should realize that any bitterness is in himself, not in medicine. Some of us want to make the National Health Service work properly. We know there are plenty of flaws in it—especially in general practice and in the overproduction of specialists—but we think that the flaws will be repaired the more quickly if we use logic rather than emotion as our tool and avoid using words and phrases designed to excite emotion instead of those which will promote critical analysis.—I am, etc.,

Teddington, Middlesex.

GEORGE DISCOMBE.

Payment of Dispensing Doctors

SIR,—I am interested and at the same time disturbed to learn from Dr. J. J. Hamilton (*Supplement*, January 12, p. 15) that my scheme for dispensing payment is bureaucratic in conception and sacrifices the substance of independence for the shadow of salaried security. I appear to have trodden on his ideological corns. Can it be that he foresees, and fears the day when our ration of State-approved drugs, issued strictly according to the approved scale, is delivered in a plain van by a minor official of the medicaments branch of the Ministry of Health?

Surely it does not need a time-and-motion study to prove that the system of dispensing against Forms E.C.10, which are filled in, sorted, and sent quarterly to the Pricing Bureau, is a time-consuming business which few of us would care to undertake. On this question I am prepared to stand or fall by the majority vote of my fellow rural practitioners. Already an oppressive amount of paper work falls to our lot, and if Dr. Hamilton does not find this extra burden irksome he possesses a facility for form-filling and filing—to follow his illiterate style—which I for one admire but do not envy.

As N.H.S. practitioners we accept a capitation fee for medical attention to our patients. Since the actual dispensing of medicines is a labour not undertaken by our urban colleagues, what could be more logical than an additional capitation fee for this service, particularly as the volume of work is in proportion to the number of dispensing

patients on our lists? Introducing the profit-and-loss motive on the actual cost of drugs, by whatever method payment is made, puts us at additional risk compared to urban practitioners, and I cannot understand Dr. Hamilton's objection to the removal of this risk. If such a capitation fee is sufficient to pay the salary of a dispenser, it can of course be applied in this way. But I very much doubt if it is the official viewpoint that the dispensing doctor shall compensate for his sparse and scattered practice by making money on the drug account. Surely it is the mileage fund which was designed to equalize the positions of the urban and rural practitioners? I contend that my scheme would give the dispensing doctor recompense for his labour without adding to his administrative work, and at the same time give him the same freedom to prescribe the drugs of his choice that is enjoyed by his urban counterpart. If Dr. Hamilton objects to a capitation fee on principle, I wonder how he reconciles himself to N.H.S. practice.—I am, etc.,

Newbury, Berks.

JOHN RICHARDS.

Telling the Public

SIR,—G.P.s all over the country will warmly welcome Dr. S. Wand's address (*Supplement*, January 12, p. 9) at the fourth annual meeting of the Executive Councils Association (England) on the subject of educating the public about the uses and abuses of the National Health Service. I have myself made suggestions on identical lines, both to the B.M.A., through the courtesy of the *Supplement*, and to my local medical committee, but received no sympathy from either body.

As it will no doubt take years for Dr. Wand's suggestions to be reflected in appropriate action by executive councils, may I be permitted to make the following suggestion? It is that immediate steps be taken by the B.M.A. to arrange for a broadcast by the B.B.C. It might be entitled, "How to help your doctor and yourself." It should be done by a medical man with ample experience of a G.P.'s difficulties. Presumably the medical man would have to be anonymous, but those of us who have read Dr. Wand's vigorous address would have no difficulty in choosing our man for the job.

May I add as a footnote an experience of my own. One Sunday at 12 noon, when I had finished my round and changed into gardening kit, I was called to see a patient who had been ill for two days. When I pointed out that the call should have been received by 10 a.m., the patient apologized but said that she did not know the rules. When I was leaving the house I suggested that as the chemist shuts at 1 p.m. someone had better come into town with me in my car to fetch the medicine. The reply was that that would not be convenient, "but Mr. X, the chemist, lives only a few doors away and he won't mind going back to town in the afternoon to open his shop for us."—I am, etc.,

Inverness.

D. R. MACDONALD.

Tracing Patients

SIR,—There is one point in this "Hunt the Patient" game that I have not noticed being touched on. If the point has been fully considered, just destroy this letter.

I understand that the absentees are being so classified by consulting the food office records. Now there is, and always has been, a floating population of people who have left the areas of Drs. A, B, and C, and gone to the areas of Drs. D, E, and F, and vice versa, but have not signed on with the doctors in their new area.

Before this new game started, the numbers who had left the areas of Drs. A, B, and C and not signed on with Drs. D, E, and F balanced out with the ones who had left the areas of Drs. D, E, and F, and had not yet signed on with Drs. A, B, and C. But this new scheme seems to me to be just a grossly unfair and underhand method of reducing the capitation fee indirectly.

Am I right, or have all the newcomers to an area's ration list been put on the list of some doctor in that area?—I am, etc.,

Stratford-upon-Avon.

FILMER COLEMAN.

Difficult Undertaking

SIR,—As it is possible for a G.P. with an average list of 2,500 to earn from £2,000 to £2,500 a year gross (£40 to £50 a week), it is unwise for Dr. H. Firman (*Supplement*, January 12, p. 14) to compare our case with workers earning less than a quarter of these amounts. Has Dr. Firman ever envisaged the possibility of an impartial tribunal considering our "relative remuneration" excessive and recommending a cut?

It behoved our representatives to establish as strong a case as possible for increased payment before going to arbitration. This has taken much preparation and time in collecting facts from all over the country. Let us hope they will be successful in what must prove a difficult undertaking in these times of governmental financial stringency.

Our representatives spend much time and trouble voluntarily on our affairs. Rather than reviling them, let us encourage and help them by paying our voluntary levies to local medical committees (which can remain free from Ministerial control only by paying their own expenses) and wishing them success in their labours on our behalf.—I am, etc.,

Birmingham.

WM. WATSON NEWTON.

Diagnostic Unit in General Practice

SIR,—I very recently qualified from a London hospital and intend to go into general practice. It had seemed from what I had seen and heard in the last two months that in general practice in England to-day it was all too easy to forget all the scientific medicine one had ever learnt. Therefore I was particularly interested in your report of Dr. John H. Hunt's stimulating account of his own diagnostic unit (*Journal*, December 29, 1951, p. 1575). A practitioner who need not surrender his patient while simple laboratory tests are done must add immeasurably to the interest of his work besides saving the time of hospital and patient. I would like to thank Dr. Hunt for his fine example, and hope that many, including myself, may follow it.—I am, etc.,

London, S.E.22.

UNA FREESTON.

According to Rule

SIR,—The other day I issued a final N.H.S. certificate to a railwayman at the end of a brief incapacity due to a car injury. He attended next day stating that he could not resume because one week's notice of intention to do so was required, presumably to allow of his being examined by some medical officer so much wiser than the poor ignorant practitioner. The Ministry of National Insurance, to which I reported this unintelligent action, has undertaken to pursue the matter. But is it not incredible that British Railways should be content to keep employees idle in their houses, drawing, I suppose, State money? The patient, too, is gratuitously told that his doctor's certificate is not believed.—I am, etc.,

Chesterfield.

A. H. DRIVER.

POINTS FROM LETTERS

Speedy Settlement

Dr. G. H. A. ROBINSON (Darlington, Co. Durham) writes: How very refreshing it was to read the letters of Dr. H. Firman (*Supplement*, January 12, p. 14) and Mr. Donald M. O'Connor (p. 15). Timid, yes, frustrated certainly, and tired most certainly we are, but even the most timid animal will turn and fight when cornered. . . . Is it impossible for us to elect someone willing to fight for our rights—someone perhaps who is suffering himself from our injustices and grievances? . . . We are members of the strongest "union" in the world; let us find the right leader (and pay him if necessary) and we would all follow him to victory, before our children are too old to appreciate the advantages the profession was once able to bestow upon them. We are filled with neither greed nor avarice, but we require and demand a speedy settlement of our just claims—not in years or months, but now.

Association Notices

AREA OF BRADFORD AND DEWSBURY DIVISIONS

Notice is hereby given by the Council of the Association to all concerned that it is proposed to transfer the Civil Parish of Liversedge from the area of the Bradford Division to that of the Dewsbury Division.

Any member affected by this proposal and objecting thereto is requested to write to the Secretary of the Association by March 1, 1952.

A. MACRAE,
Secretary.

Branch and Division Meetings to be Held

CHELSEA AND FULHAM DIVISION.—At Roebuck Hotel, Chelsea, S.W., Friday, February 8, 8.30 p.m., annual B.M.A. Lecture by Mr. A. E. Roche: "Genito-urinary Generalities," with demonstration of x-ray films.

CHESTERFIELD DIVISION.—At Lecture Room, Walton Sanatorium, Matlock Road, near Chesterfield, Friday, February 8, 8.45 p.m., discussion: "The Relief of Pain in Inoperable Cancer and Allied Conditions." Mr. G. W. Blomfield and Mr. J. Hardman will each speak.

COVENTRY DIVISION.—At Gymnasium, Coventry and Warwickshire Hospital, Tuesday, February 5, 8.30 p.m., ordinary general meeting. Lecture by Professor H. C. McLaren: "Post-natal Symptoms of Importance."

DUDLEY DIVISION.—At Queen Mary Ballroom, Dudley, Wednesday, February 6, 7.30 for 8 p.m., dinner-dance arranged by Dudley and Stourbridge Pharmaceutical Society. Members of the Dudley Division, B.M.A., are invited.

HAMPSTEAD DIVISION.—At New End Hospital, Heath Street, London, N.W., Wednesday, February 6, 8.30 p.m., talk by Dr. Henry Yellowlees: "Hypnotism—its Uses and Limitations in Medicine."

MID-HERTS DIVISION.—At Red Lion Hotel, St. Albans, Friday, February 8, 8.45 p.m., meeting.

NUNEATON AND TAMWORTH DIVISION.—At Red Lion Hotel, Atherstone, Tuesday, February 5, 8 p.m., dinner; 9 p.m., B.M.A. Lecture by Sir Clement Price Thomas: "The Diagnosis and Treatment of Carcinoma of the Lung."

REIGATE DIVISION.—At Redhill County Hospital, Tuesday, February 5, 8.30 p.m., clinical evening.

SALISBURY DIVISION.—Tuesday, February 5, annual medico-legal dinner.

SOUTH-EAST ESSEX DIVISION.—At Southend General Hospital, Friday, February 8, 8.30 p.m., address by Miss Eileen Whapham: "Cases at Gynaecological Out-patients."

SOUTH STAFFS DIVISION.—At Rendezvous Restaurant, Berry Street, Wolverhampton, Tuesday, February 5, 8 p.m., supper meeting. Lecture by Professor Brodie Hughes: "The Significance of Subarachnoid Haemorrhage and its Surgical Treatment."

WEST MIDDLESEX DIVISION.—At Nelson Room, Town Hall, Ealing, W., Thursday, February 7, 8.30 p.m., meeting to discuss the possibility of resignation from the B.M.A. of members of the West Middlesex Division in the event of failure to complete arbitration within a reasonable period.

Meetings of Branches and Divisions

HONG KONG BRANCH

In the session 1950-1 the Hong Kong Branch held well-attended clinical meetings on sprue, infections of the hand (with film), and the use of streptomycin in the treatment of pulmonary tuberculosis. Two clinical evenings were also held at Queen Mary Hospital and one at the Royal Naval Hospital.

Two old minute-books of the Branch have been found dating back to the time of Sir Patrick Manson.

Captain Geoffrey C. H. Crawshay, D.L., J.P., has on medical advice resigned the chairmanship of the Welsh Board of Health, which he has held since 1945. Captain Crawshay is president of the South Wales and Monmouthshire Council of Social Service and chairman of the Welsh Rural Industries Committee of the Monmouthshire Rural Community Council. He is also a member of the Council of the University College in South Wales.

A new pleasantly flavoured elixir for the menopausal patient

Estigyn Elixir is a pleasantly flavoured preparation incorporating all the advantages of ethinyl oestradiol—full activity by mouth and noticeable increase in mental and physical well-being following administration.

It is acceptable to patients who experience difficulty in swallowing tablets, and it also facilitates a gradual reduction in dosage as the patient attains a balanced hormonal level.

Commonly used sedatives such as phenobarbitone sodium and bromides may be added in appropriate doses when indicated.

'ESTIGYN' ELIXIR

Containing 0.02 mg. Ethinyl Oestradiol B.D.H.
in 60 minims (one teaspoonful)

DOSAGE—One teaspoonful thrice daily, modified according to response
Bottles of 4 fl. oz. and 40 fl. oz.

Literature and specimen packings are available on request to the

Hot water for washing — hands, instruments, utensils — in surgery, ward and hostel — the need is constant. Ascot gas water heaters meet that need — cheaply. They are fully automatic, they give hot water instantly and in endless quantity, and they use gas only while hot water is running.

The RS 52/1 is of particular value. It provides water controlled by a knob at warm, hot or *boiling*; certified by public analyst to be fit for human consumption.

See the full range of Ascot heaters at any gas showrooms or write for illustrated leaflets to

AN ADJUVANT IN THE THERAPY OF INFERTILITY

Nutri-Sal

In the absence of organic deficiencies or pathogenies, hostile genital secretions may apparently cause infertility merely through immobilization of sperm.

In these cases Nutri-Sal—a physiologic glucose douche powder—encourages a more favourable environment, and supplies metabolic stimulus for sperm motility.

Clinical tests have shown that in such cases, where pregnancy *can* occur, a pre-coital douche of Nutri-Sal will often promote fertility.

...A Complete Response
in HYPERTENSION

**THE BLOOD PRESSURE
DROPS**

Through reduction of peripheral resistance, Veriloid produces a significant drop in arterial tension. Not only is that large group of patients with moderate hypertension benefited, but also patients with severe essential and malignant hypertension. The usual daily requirement of Veriloid is from 9 to 15 mg., given in divided dosage three times a day, at intervals of from 6 to 8 hours, the first dose to be taken after breakfast. The evening dose should be one or two mg. larger than the other two doses of the day.

**THE PATIENT IMPROVES.
SUBJECTIVELY**

The gratifying feature of Veriloid therapy is the speed with which the distressing discomfort of hypertension is overcome. Headache disappears, easy fatigability lessens, vision has been reported to improve through absorption of retinal exudations and kidney function is increased. These beneficial changes, often experienced before the blood pressure has dropped significantly, are presumably related to the vaso-relaxation induced by Veriloid and the resulting improved tissue nutrition. Veriloid is available on prescription only through all pharmacies in 1.0 mg. tablets in bottles of 100 and may be prescribed on Form E.C.10 without restriction. Literature available on request.

Lucozade . . . an antidote to melancholy

Lucozade can transform low vitality and a pessimistic outlook into liveliness and self confidence. Lucozade gives the energising and restorative properties of glucose with an attractive and sparkling flavour which overcomes any antipathy to plain glucose. Lucozade is glucose in so delightful and refreshing a form that adults and children alike need no persuasion to take it as recommended.

Pre-Natal Diet and the course of Pregnancy

The normal functioning of the reproductive organs during pregnancy depends, among other things, upon the plentiful intake of vitamins and minerals.

Medical opinion is gaining ground that there is an increased need for Vitamin B in late pregnancy and the early puerperium. Its administration during the period before childbirth has resulted in less vomiting and nausea and in marked improvement in the nutritional value of the breast milk. In order to assure the building of the foetal bones *in utero* and afterwards during breast-feeding, the importance of Vitamin D and of calcium and phosphorus is also established.

In Supavite Capsules the practitioner has at hand a combination of these and other essential vitamins and minerals in a scientifically balanced form of particular value in maternity cases.

POLLERGEN (DUNCAN)

A COMBINED POLLEN EXTRACT

indicated in

● SEASONAL HAY FEVER ● CORYZAL ASTHMA

Researches in Allergy have clearly demonstrated that more success is to be achieved by treatment with a combined pollen extract than with simple extracts of pollen such as Timothy Grass.

Pollergen is a combined extract of those pollens which have proved to be most frequently responsible for the onset of Hay Fever and Hay Asthma, and treatment should be commenced early in the year so as to ensure that maximum dosage is attained before the Pollen Cloud is at its height.

Literature and prices on application.

fundamental principles of *Spirella* design

A garment designed on Spirella's Exclusive Principle supports the figure by supplementing the mechanical action of the abdominal and dorsal muscles. Even when muscles have become relatively toneless their natural action is reproduced with the aid of garments designed to have their fixed positions of support corresponding to the bones of the pelvis and spine. The soft tissues around the hips are moulded into pleasing curves and the intestines and other internal organs supported in their healthiest positions, without constriction.

*It depends what
you mean by 'Banking'*

OF COURSE we safeguard money and cash cheques. But we go further. We maintain specialist departments whose functions, although not 'banking' in the usual sense, can nevertheless be used to very good purpose. These departments will, for example, act as your Executor, help with your Income Tax problems, obtain your currency when you travel abroad. They will do many more things besides. But the moral of this multiplicity of functions is simply this: if you have any problem of finance or business, the chances are that we can help you deal with it. And that is what we mean by 'banking'

APPOINTMENTS

Applicants should state name, address, age, nationality, qualifications, and enclose 3 copies (unless otherwise specified) of recent★ testimonials with short statement of experience and appointments held.

Applications should be sent at once if no closing date is given.

Canvassing in any form will disqualify.

★SERVICE MEMBERS may have difficulty in supplying recent testimonials, but this should not deter them from applying.

Deferment of call-up for "R" practitioners (i.e., practitioners liable for call-up under the National Service Acts) is granted at the discretion of the Central Medical War Committee and (in Scotland) the Scottish Central Medical War Committee. The Committees normally allow an "R" practitioner to hold a First House Officer post (N.H.S. salary £350 per annum) provided that he obtains it without delay. Under present arrangements the Committees also normally allow an "R" practitioner to hold a Second House Officer post (£400) and a Senior House Officer post (£670), provided in each case that the higher appointment is secured before the termination of the practitioner's current appointment.

"R" practitioners may not accept Third House Officer posts (£450 per annum) unless they have obtained the special permission of the C.M.W.C. or (in Scotland) the Scottish C.M.W.C.

SALARY SCALES OF JUNIOR GRADES OF HOSPITAL MEDICAL STAFF

Registrar Grades, Whole-time

(a) **REGISTRAR**: Posts obtained normally not less than two years after registration as a medical or dental practitioner and held normally for two years: £775 per annum in the first year; £890 per annum in the second and any subsequent years.

(b) **SENIOR REGISTRAR**: Posts obtained normally not less than four years after registration as a medical or dental practitioner and held normally for three years: £1,000 per annum in the first year; £1,100 per annum in the second year; £1,200 per annum in the third year; £1,300 per annum in any subsequent years.

Other Grades, Whole-time

(a) **HOUSE OFFICER**: £350 per annum for the first post held, £400 per annum for the second post held; £450 per annum for the third and any subsequent post held; with, in each case, a deduction at the rate of £100 per annum in respect of board and lodging and other services provided. Each post shall be tenable for six months.

The Minister will be prepared to authorize, in exceptional circumstances, salaries up to £50 per annum higher than the standard rates specified above where a post cannot be filled otherwise.

(b) **SENIOR HOUSE OFFICER**: Posts obtained normally not less than one year after registration as a medical or dental practitioner and normally held for one year only: £670 per annum.

(c) **JUNIOR HOSPITAL MEDICAL OFFICER**: Officers who have held house appointments but who are not registrars and who have less responsibility than other hospital officers of non-consultant status: £700 (for an officer appointed not less than two years after registration as a medical practitioner) by £50 to £1,000 per annum.

ALL NATIONAL HEALTH SERVICE HOSPITAL APPOINTMENTS ARE IN ACCORDANCE WITH THE TERMS AND CONDITIONS OF SERVICE OF HOSPITAL MEDICAL STAFF

Those intending to apply for resident appointments in the Registrar grades are recommended to make inquiries with regard to the deductions proposed for board and lodging at the time of submitting their applications, where this is not stated in the advertisement.

Applications are invited from registered women medical practitioners for the post of
ASSISTANT MEDICAL OFFICER
(Maternity and Child Welfare) in the Health Department

Successful applicant will work under the Senior Assistant Medical Officer for maternity and child welfare, take duties in the antenatal, infant welfare, toddlers and immunization clinics and such other duties as the Medical Officer of Health may direct. Experience in obstetrics and gynaecology or diseases of children desirable. Possession of the D.R.C.O.G. or D.C.H. an advantage. Salary scale £850 by £50 to £1,150. Medical examination on appointment to conform with Local Government and Other Officers' Superannuation Act, 1937. Officers of the Corporation are expected to belong to an appropriate organization as referred to in para. 44 of the Charter. Applications (no forms provided), with two recent copy testimonials, to the Medical Officer of Health, Council House, Coventry, by February 11, 1952. (7300)

ISLE OF WIGHT COUNTY COUNCIL

Applications are invited from registered medical practitioners, men or women, for appointment as **ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER**. Candidates should possess D.P.H. or D.C.H. and experience in the ascertainment of educationally retarded children will be an advantage. Salary will be on the scale £850 rising by annual increments of £50 to a maximum of £1,150 per annum. The person appointed will be entitled to a travelling allowance on the Council's scale for the use of a car. Duties will be mainly in connexion with Maternity and Child Welfare and School Medical Services, together with such other duties as may from time to time be assigned by the County Medical Officer. Forms of application, obtainable from the undersigned, should be returned completed, together with a copy of one recent testimonial, and the names of two persons to whom reference may be made, not later than February 21, 1952.—L. H. Baines, Clerk of the County Council, County Hall, Newport, I.W. (7368)

KENT EDUCATION COMMITTEE

ASSISTANT COUNTY MEDICAL OFFICERS
Applications are invited for the above appointments in the Erith, Sittingbourne and Canterbury districts. The salary scale is £850 a year, with annual increments of £50 to £1,150 a year. The commencing salary will be fixed at a point on the scale according to the experience and qualifications of the successful candidate. The appointments are superannuable and the successful candidates will be required to pass medical examinations. The duties are mainly in the school health and child welfare services. Applications, stating age, qualifications and experience, accompanied by the names and addresses of two persons to whom reference may be made as to professional ability and character, should be addressed to the County Medical Officer, County Hall, Maidstone, not later than February 14.—A. Elliott, M.D., County and School Medical Officer, County Hall, Maidstone. (7443)

MIDDLESEX COUNTY COUNCIL

County Health Department
SENIOR ASSISTANT MEDICAL OFFICER
(Female)

Required initially in Area 10 (Twickenham, Feltham, Staines and Sunbury). Responsible for some of the administrative work in health visiting, midwifery, home nursing and day nursery services, and some clinical work. Must be prepared, if required, to undertake also duties of Medical Officer of Health or Deputy of one or more of the County Districts in Area, in which case salary would be amended as appropriate nationally negotiated scale. Established, pensionable, whole-time post. Subject to medical assessment and prescribed conditions. Salary as Whitley Council, £1,150 by £50 to £1,400 per annum inclusive. Previous service in same grade would be considered in determining commencing salary. Applications (no forms), stating age, qualifications, experience, two referees, to Area Medical Officer, Elmfield House, High Street, Teddington, by February 16 (quoting K.394 B.M.J.). Canvassing disqualifies.—C. W. Radcliffe, Clerk of the County Council. (7156)

Applications are invited from fully qualified registered medical practitioners for the post of
WHOLE-TIME ASSISTANT SCHOOL MEDICAL OFFICER

Salary scale £850 to £1,150 per annum by annual increments of £50. The duties will consist of routine medical inspection in schools and clinic work. Experience in refraction work is desirable. The appointment is subject to the provisions of the National Health Service (Superannuation) Regulations and is terminable by one month's notice on either side. The successful candidate will be required to pass a medical examination. Forms of application, which may be obtained from the undersigned, should be completed and returned as soon as possible.—H. Dibden, Chief Education Officer, Town Hall, Hanley, Stoke-on-Trent. (6971)

SMETHWICK, COUNTY BOROUGH OF

Applications are invited from registered medical practitioners for the post of
ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER
The duties will consist mainly of work in connexion with maternity and child welfare and school medical inspection. The duties will also include such other public health work as the Medical Officer of Health may direct. Salary will be on the scale £850 per annum, rising by £50 annually to a maximum of £1,150 per annum. The appointment will be subject to the provisions of the Local Government Superannuation Act, 1937, and the successful candidate will be required to pass a medical examination. The appointment will be subject to two months' notice on either side. The officer appointed may, if desired, be offered the tenancy of an unfurnished flat. Forms of application may be obtained from the Medical Officer of Health, Public Health Department, Hales Lane, Smethwick, to whom they should be returned within two weeks of the publication of this advertisement.—E. L. Twycross, Town Clerk, Council House, Smethwick. (7157)

ADMINISTRATIVE**SCOTLAND, SOUTH-EASTERN REGIONAL HOSPITAL BOARD**

Applications are invited for the post of
ASSOCIATE MEDICAL SUPERINTENDENT to West Lothian Hospitals Board of Management
The duties will consist of the medical administration of some 1,000 general beds, mainly in Bangour Hospital (situated 17 miles west of Edinburgh). Salary will be at the rate of £1,400 per annum, rising by annual increments of £50 to £1,750. Applications, together with the names of three referees from whom confidential reports may be obtained, should be submitted to the Secretary, South-Eastern Regional Hospital Board, Scotland, 11, Drumsheugh Gardens, Edinburgh, 3, from whom further particulars regarding this post may be obtained, within thirty days. (7592)

GOVERNMENTAL**TREASURY MEDICAL SERVICE**

Applications are invited from medical practitioners, practising in the districts detailed below, for appointment in a part-time and mainly advisory capacity, as

LOCAL TREASURY MEDICAL OFFICER

for each of the places or groups of places shown. The town shown in brackets after the place-names indicates the Head Post Office area in which the place, or group of places, is situated. Successful applicants will be required to examine and report on the condition of certain Government officers, teachers, candidates for appointment, etc., who may be referred to them from time to time; and to attend when summoned to an emergency case of accident or sudden illness occurring in a Government office in the neighbourhood. Fees for this work, and mileage allowance where necessary, will be paid on a scale agreed with the British Medical Association. Intending applicants should write, within 14 days, to: Treasury Medical Adviser, Treasury Chambers, Whitehall, S.W.1, for a form on which application may be made. Applicants should be not more than 60 years of age. The places for which applications are invited are as follows:

England and Wales

Golders Green (London, N.W.11)
Askern, Campsall, Norton and Womersley (Doncaster)

Kidwelly (Llanelli)**Longtown (Carlisle)****Scotland**

Carnoustie (Dundee)
Portree (Portree). (7578)

SERVICES**ROYAL NAVAL MEDICAL SERVICE**

Candidates are invited for service as
MEDICAL OFFICERS
in the Royal Navy—preferably below 28 years. They must be British subjects whose parents are British subjects, and be medically fit. No examination will be held but an interview will be required. Initial entry will be for four years' short service, after which gratuity of £600 (tax free) is payable, but permanent commissions are available for selected short service officers. Officers entered on or after January 1, 1951, will be eligible to be considered for antedates of seniority up to two years for service in recognized civil hospitals, etc. For full details apply Medical Director-General, Admiralty, S.W.1.

INDUSTRIAL APPOINTMENTS**FACTORY DOCTORS**

The following appointments as Appointed Factory Doctor under the Factories Acts, 1937 and 1948, are vacant: Kirkcaldy, in the County of Fife; Brill, in the County of Buckingham; St. Agnes, in the County of Cornwall. Applications, which should be received not later than February 16, 1952, should be sent to the Chief Inspector of Factories, 8, St. James's Square, London, S.W.1.

LEVER BROTHERS & UNILEVER LIMITED.

Applications are invited from registered medical practitioners of either sex for the full-time post of **Assistant Medical Officer (at head office)**. The successful candidate will be required to assist the head office staff medical officer in the health supervision of a large clerical staff, a considerable proportion of whom are adolescents. The work will also include the medical examination of candidates for home and overseas appointments, the re-examination of employees and their families on home leave from both temperate and tropical climates and the health supervision of certain nearby small industrial units. Candidates should have a good standard of clinical medicine combined with an interest in preventive and industrial medicine. Commencing salary will be in accordance with experience, qualifications and age and will be not less than £1,100 per annum. Letters of applications, which should include the names of three persons to whom reference may be made, and full details of the candidate's training and career, should be submitted not later than February 16, 1952, to the Principal Medical Officer, Unilever House, London, E.C.4. (7595)

NATIONAL COAL BOARD, DURHAM DIVISION.

Applications are invited from registered practitioners for a full-time appointment as a **Medical Officer** in the Durham Division of the National Coal Board. The duties will embrace the normal functions of Industrial Medical Officer. The successful candidate will be allocated to an area and will be responsible for the organization and supervision of the medical and first-aid services at the collieries in that area. Candidates should have had experience in general practice and/or in the field of preventive and industrial medicine. Knowledge of the coalmining industry, though not essential, will be an advantage. Salary will be within the range of £1,250 to £1,900, according to qualifications, age, and experience. Applications, giving full particulars of age, qualifications, experience, in chronological order, present post and salary, together with the names of three referees, or three testimonials, should be sent to the Establishments Officer, National Coal Board, "D" Floor, Milburn House, Newcastle-upon-Tyne, 1, within fourteen days of the appearance of this advertisement. Original testimonials should not be sent.

NATIONAL COAL BOARD, NORTH-WESTERN DIVISION.

Applications are invited for the two posts of **Medical Officer** to the No. 2 (Wigan) Area and the No. 3 (St. Helens) Area. The work will include making underground visits to collieries. Candidates should have experience in the field of preventive and industrial medicine; knowledge of the coalmining industry will be an advantage. Salary will be according to qualifications and experience, within the range of £1,250 to £1,900. Applications, giving age, education, qualifications, experience, present appointment and salary, together with the names of two referees, should be sent to the Divisional Establishment Officer, National Coal Board, 40, Portland Street, Manchester 1, by February 11, 1952. (7247)

RADIOLOGIST

to the above 300-bed midwifery and general hospital for women and children. Salary range £1,500 to £2,000 per annum, according to experience. Full- or part-time appointment, with or without limited private practice. Applications, stating age, nationality, qualifications and experience, and enclosing copies of at least three testimonials, and photograph, must be received by the undersigned on or before March 31, 1952—Nell Stephenson, Acting Manager and Secretary. (7601)

ROAN ANTELOPE COPPER MINES

Northern Rhodesia
MEDICAL OFFICER

Preferably with experience in modern general anaesthesia, for Company's European and African hospitals, catering for community of approximately 3,500 Europeans and 26,500 Africans. Basic salary from £1,200 per annum depending on qualifications and experience, plus cost-of-living allowance (at present £90 per annum), and copper bonus scheme (at present approximately equivalent to £650 per annum). Also pension and life assurance benefits. Write Mine Employment Department, Selection Trust Building, Mason's Avenue, E.C.2. (7579)

HIS MAJESTY'S COLONIAL SERVICE

Applications are invited from male medical practitioners of British nationality possessing qualifications registrable in the United Kingdom for appointment as

RESIDENT MEDICAL OFFICERS (Interns)

at the King George VI Hospital, Nairobi. Appointment will be on agreement for one year in the capacity of a House Physician or House Surgeon. These posts are interchangeable by mutual agreement after six months' experience in either. Officers should preferably be under the age of 30 and single; married, they should not be accompanied by their wives. "R" practitioners should have completed their period of National Service before applying. Salary £300 a year for the first six months and 350 a year for the second six months. In addition a messing allowance of £144 a year is payable, income tax at local rates. Furnished quarters including linen, cutlery, china and glassware, together with light, fuel, and water, are provided free of charge. Free passages are provided on appointment, and on satisfactory completion of internship. Eighteen days local leave a year is granted. If selected candidates apply for and obtain appointment to the Colonial Medical Service in Kenya at the expiration of their internships, previous service as Resident Medical Officers will count for leave, but they will be required to serve a usual probationary period. The period of internship will not count for seniority. Ample opportunities for clinical experience with systematic teaching and a large measure of personal responsibility under specialist guidance is afforded. Candidates should apply (or forms of application to the Director of Recruitment (Colonial Service), Sanctuary Buildings, Great Smith Street, London, S.W.1) quoting reference No. 27215/333/1951. (7576)

HIS MAJESTY'S COLONIAL SERVICE, Malaya

Doctors having medical qualifications registrable by the General Medical Council in the United Kingdom, with one or more years' experience after qualification, are required for appointment as

MEDICAL OFFICERS and MEDICAL OFFICERS OF HEALTH

for general medical and health duties. A limited number of practitioners liable for call up under the National Service Act, 1948, may apply, and if appointed will be granted indefinite deferment of call up on completion of a minimum period of one tour of three years in the Malayan medical service. Appointment is available (a) on probation for permanent establishment, (b) on employment from the National Health Service, and (c) on short term contract with gratuity. (a) **Permanent terms.** Subject to three years' probation, appointment is permanent with pension (non-contributory) at age 55. Salary is paid in the scale 1952 by £42 to £1,204 to £1,274 by £42 to £1,652 per annum. There are many posts, specialist and administrative, available on promotion carrying higher salaries (up to about £2,400 for the highest post). Promotion is often made before reaching the top (£1,652) of the long scale. There is also a cost-of-living allowance at varying rates, according to family circumstances, subject to maximum of £336 per annum for single men and of £707 per annum for married men with children (both rates higher when stationed in Singapore). Note. Doctors with more than one year's approved experience after age 25 (including service in His Majesty's Forces) enter the salary scale at points above the minimum according to their experience; and four increments of salary are also given to holders of approved higher qualifications (e.g. F.R.C.S., M.R.C.P., D.P.M., D.A., etc.). (b) **National Health Service.** Doctors may resign from the National Health Service but retain their superannuation rights during their time in Malaya (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their Malayan salary on leaving Malaya at the end of their engagements. Emoluments as under (a) including incremental credit for experience and higher qualifications as in note under (a). Doctors so appointed may be considered for permanent terms at any time during their Colonial employment provided they surrender their rights to the resettlement grant and payment by Malayan Governments of superannuation contributions. (c) **Contract terms.** The contract will be for three years' resident service, renewable for a further tour of three years by mutual agreement. Salary and cost-of-living allowance as under (a) including incremental credit for experience and higher qualifications as in note under (a). In addition a gratuity earned at the rate of £300 to £450 per annum, according to salary, is paid on expiry of contract. Doctors on contract may be considered for appointment to the permanent establishment at any time on their agreeing to surrender their gratuity earning rights. In all three types of appointment the rates of salary and gratuity refer to doctors eligible for expatriate terms under Malayan Regulations (i.e. those whose permanent homes are in the United Kingdom, Ireland, Australia, Canada, etc.). The climate is, for the tropics, healthy. European children do well up to the age of about six and schools are available locally. Income tax is payable at Malayan rates which are lower than those in the United Kingdom. Government quarters with heavy furniture are provided at a low rental, or an allowance is paid in lieu of quarters. Free passages are provided for the doctor, his wife, and children under the age of ten (not exceeding four persons besides himself) on appointment and once each way during each tour of duty of three to four years. Generous home leave is granted and local leave is permissible. The social and recreational facilities in Malaya are good. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/242/51). (5187)

UNIVERSITY OF HONG KONG

Applications are invited immediately for the post of

SENIOR LECTURER IN ANAESTHETICS

a post occasioned by expansion to the present establishment. Emoluments (for a married member of the staff normally resident outside Hong Kong or China, and inclusive of allowances) £1,576 by £40 to £1,736 per year. The applicant should be of consultant status and should possess a higher qualification in anaesthesia. The duties will consist of the administration of anaesthetics in the Queen Mary Hospital, the organization of teaching and research in anaesthesia. Limited consulting anaesthetic practice will be permitted. First class sea passages, and furnished houses or flats at reasonable rentals are provided for expatriate staff. Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 5, Gordon Square, London, W.C.1. The closing date for the receipt of applications is March 31, 1952. (7594)

BERMUDA

An experienced qualified

PSYCHIATRIST

is required in a part-time capacity, to supervise diagnosis and treatment in Government Institutions including a mental hospital, and to advise in the school medical service. He will be free to practice as a consultant in the Islands. There is no qualified psychiatrist at present in practice. Salary from the Government will be according to qualification and experience, but will not be less than £1,000 per annum, free of tax. For further particulars, application should be made to the Director of Health Services, Health Department, Bermuda. (7602)

HIS MAJESTY'S COLONIAL SERVICE

Gold Coast

MEDICAL OFFICERS OF HEALTH

Required for duty in the Medical and Public Health Department of the Gold Coast. Duties include Medical Officer of Health in (a) a port or large town; (b) in a mining, industrial, or rural area; or (c) as a Medical Officer of Health in epidemiology in epidemic teams. Candidates must possess a diploma or certificate in public health. Appointment can be made on a permanent basis with pension (non-contributory) at the age of 45 to 55, or on short term contract with gratuity (reckoned at £37 10s. for each completed period of three months' service) on completion of satisfactory service. Candidates in the National Health Service, on appointment to the Colonial Service, may resign from the National Health Service but retain their superannuation rights during their time in the Gold Coast (up to six years) and receive a resettlement grant of 20 per cent of the aggregate of their colonial salary on leaving the Gold Coast at the end of their engagement. Salary scale for pensionable employment ranges from £890 to £1,600 per annum, and for short term contract from £1,030 to £1,800 per annum, with gratuity or National Health Service resettlement grant. Starting salary will be determined according to age, qualifications, and experience. Quarters are provided at rental of £90 to £150 per annum. Free passages in both directions for officer and wife, and assisted passages for children. Income tax at local rates. Tour of service is 18 months. Local leave is permissible and generous home leave is granted after each tour. Candidates must have at least one year's experience after qualification. Application forms can be obtained from the Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (quoting reference No. 27215/104/51). (7575)

UNIVERSITY APPOINTMENTS**NUFFIELD FOUNDATION**

The Nuffield Foundation invites applications from citizens of the United Kingdom for

FELLOWSHIPS AND SCHOLARSHIPS IN DENTISTRY

To help the advancement of teaching and research on dental health and disease, the Foundation is prepared to award a number of Fellowships (i) to enable selected men and women with dental qualifications to receive such additional training in pure and applied science as is desirable to fit them for an academic career in dentistry, and (ii) to enable selected university graduates in medicine and science to receive training that will qualify them to undertake teaching and fundamental research on dental health and disease. The Foundation is also prepared to award a limited number of Scholarships to assist students of outstanding ability attending a university dental school to devote one or two years to further studies of the basic sciences. Applications for fellowships should be received by March 1 annually and for scholarships by June 30 annually. Copies of the conditions of both fellowships and scholarships and the application forms are obtainable from the Secretary, The Nuffield Foundation, 12 and 13, Mecklenburgh Square, London, W.C.1.—L. Farrer-Brown, Secretary of the Nuffield Foundation. (7124)

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL (Bacteriology Department)**ASSISTANT**

Required, medically qualified, preferably with experience of bacteriology. Duties consist of teaching and research. Salary scale £700 to £900 per annum, with superannuation benefits and children's allowance. Applications should be made immediately to the Secretary of University College Hospital Medical School, University St., W.C.1. (7528)

UNIVERSITY OF EDINBURGH

Applications are invited for the appointment of

LECTURER IN BACTERIOLOGY

whose principal duty will be the instruction of dental students. Salary scale £1,100 by £100 to £1,500, with superannuation benefit and family allowance where applicable. The successful candidate will be expected to take up duty as soon as possible. Further particulars may be obtained from the undersigned, with whom applications, together with the names of three referees, should be lodged not later than March 15, 1952.—Charles H. Stewart, Secretary to the University. (7596)

EXAMINING BOARD IN ENGLAND

by the
**ROYAL COLLEGE OF PHYSICIANS OF
LONDON**
and the
**ROYAL COLLEGE OF SURGEONS OF
ENGLAND**

Notice is hereby given that the following Examinations will commence on the dates stated below:

DIPLOMA IN CHILD HEALTH

Thursday, March 6
DIPLOMA IN MEDICAL RADIO-DIAGNOSIS
DIPLOMA IN MEDICAL RADIOTHERAPY
Friday, April 18

Applications and fees for either or both parts of an examination must reach the Secretary, Examination Hall, Queen Square, London, W.C.1, at least 21 days before Part I of the Examination begins.

FRANCIS M. STENT, Secretary. (7427)

**EDINBURGH POSTGRADUATE BOARD FOR
MEDICINE**

GENERAL SURGERY

A three months' course of postgraduate surgery is arranged to start on March 24, 1952. It is suitable for surgeons requiring a refresher course in the current outlook on general surgery, or for graduates preparing to specialize in surgery; approximately 275 hours of instruction are provided. A similar course will be held starting on September 29, 1952. Fee £31. 10s.

INTERNAL MEDICINE

A course lasting twelve weeks, suitable for graduates wishing a refresher course, or to specialize in medicine, begins on March 31, 1952. These courses consist of 320 hours' instruction, comprising lectures, clinical demonstrations and ward visits. A similar course begins on September 29, 1952. Fee £31. 10s.

Additional instruction in Clinical Paediatrics is arranged in conjunction with the course in Medicine, for which there is a small fee: the numbers are limited.

MEDICAL SCIENCES

A three months' course in Applied Anatomy, Physiology, Pathology, Bacteriology and Biochemistry will begin on June 30, 1952. This course is suitable for postgraduates wishing to take the Primary Fellowship examination, as a final preparation in these subjects. Considerable basic knowledge is highly desirable prior to taking this course. Fee £31. 10s.

**REFRESHER COURSE FOR GENERAL
PRACTITIONERS**

The nineteenth Fortnight General Refresher course for N.H.I. practitioners will start on May 5, 1952. Fee for graduates not claiming expenses from Government sources, 10 guineas.

Applications for enrolment should be addressed to Director of Postgraduate Studies, Surgeons' Hall, Edinburgh, 8. Applicants for courses, except general practitioners, should supply particulars of qualifications and postgraduate experience.

**GROCERS' COMPANY
MEDICAL RESEARCH SCHOLARSHIP, 1952**

Applications are invited for the Medical Research Scholarship awarded annually by the Grocers' Company. This is of the value of £450 for the first year of tenure and of £650 in the second, if the holder be reappointed; a further allowance of up to £100 each year is made for research expenses. Applicants must be British subjects and not over 35 years of age. Preference is given to those not holding other remunerative employment, and thus able to devote the whole of their time to the proposed research. The tenure of the Scholarship begins annually on September 1. Applications must be submitted before June 1. Further particulars and application forms may be obtained from the Clerk, the Worshipful Company of Grocers, Grocers' Hall, Princes Street, London, E.C.2. (7597)

INSTITUTE OF UROLOGY

UNIVERSITY OF LONDON

Institute of Obstetrics and Gynaecology (Incorporating the teaching facilities of Queen Charlotte's Maternity Hospital, Chelsea Hospital for Women, and the Department of Obstetrics and Gynaecology at the Postgraduate Medical School, Hammersmith Hospital)

Applications are invited from graduates with a registrable qualification, for enrolment for the Spring Term (March 10 to June 7, 1952). Graduates are allotted to one of the constituent hospitals for clinical work, and attend lectures and special demonstrations at all three hospitals. Enrolment fee £3. Tuition fee £30 for one term, £55 for two terms.

General practitioners wishing further experience in obstetrics may be accepted to attend the course at Queen Charlotte's Maternity Hospital for shorter periods (i.e. two to four weeks). They will be allowed to do normal deliveries and will have the opportunity of attending the combined classes of lectures and demonstrations at the three hospitals of the Institute. Ministry of Health grants are payable to approved general practitioners attending for a period of two weeks.

During vacation, graduates may attend the practice of the hospital at Queen Charlotte's Hospital and at the Postgraduate Medical School. Fee £1 per week.

A Refresher Course for general practitioners will be held from February 25 to March 1, 1952. Fee £5. 5s.

Hostel accommodation is available at Queen Charlotte's Hospital and at the Postgraduate Medical School.

Further particulars can be obtained from the Secretary, Institute of Obstetrics and Gynaecology, Dovehouse Street, S.W.3. (7444)

UNIVERSITY OF MANCHESTER

Faculty of Medicine
DIPLOMA IN DIAGNOSTIC RADIOLOGY
(D.M.R./D., R.C.P. and S. Eng.)

Provided a sufficient number of suitable candidates apply, a course of instruction for the above diploma will commence early in March, 1952, and extend over a period of two years. The course is full-time, non-resident, inclusive fee £52. Applications are invited from registered medical practitioners who fulfil the requirements as to previous medical experience laid down by the Examining Board in England (D.M.R./D. Regulations obtainable from the London Conjoint Board, 8-11, Queen Square, London, W.C.1). Candidates should note that no paid posts will be available during the period of training. Application to take the course should be made to the Dean of Postgraduate Medical Studies, the University of Manchester, not later than Friday, February 15, 1952. (7445)

BENGER'S FOOD

CARBOHYDRATE CONVERSION DURING PREPARATION

Benger's Food is a special farinaceous base to which active pancreatic enzymes have been added. In preparing the food, the enzyme trypsin modifies the protein of added milk so that indigestible curds no longer form in the stomach. At the same time, amylase rapidly converts the wheaten starch base of the food into soluble and easily digestible dextrins, dextri-maltoses and maltose.

Of accepted value in
 * CONVALESCENCE and in the treatment of

Lifting the veil

The distress which accompanies the menopausal years need not be allowed to go unchecked. The physician has an adequate means of relieving the several conditions which veil a woman's outlook during her middle years. The administration of SEDESTRAN is a safe and ready method of controlling these symptoms by minimal medication. Menopausal migraine and hypertension respond well to SEDESTRAN as also does dysmenorrhoea of neurogenic and psychogenic origin.

Intradex

BRITISH DEXTRAN

*A plasma substitute developed by
British Scientists in Great Britain*

The sixteen physical, chemical and biological tests, to which each batch of Intradex is subjected, ensure uniformity, sterility and freedom from toxic, pyrogenic, antigenic, anaphylactoid and cutaneous reactions.

It is interesting that each of a group of eight chinchilla rabbits, used to determine the renal excretion index, has received an average of approximately 1,000 ml. of Intradex over a period of one year. This is equivalent to approximately 125 bottles (each 540 ml.) in a human subject. All these rabbits are in excellent condition.

Biological Control

The standard for freedom from pyrogenicity is more stringent than the B.P. standard. Rabbits are injected intravenously with 20 ml. Intradex per kg. of body weight. The batch of Intradex is rejected if any single rabbit in a group of six has a rise in temperature greater than 0.6°C. within four hours of the injection.

Available in M.R.C. transfusion bottles. Intradex (Salt Free) can be supplied for paediatric use and for the treatment of nephrotic cases. Further information and literature on request.

Intradex is the brand of dextran tested by the Medical Research Council and supplied to the Ministry of Health in Gt. Britain.

Effective Protection at all times

Contains 2% Hexachlorophene

Cidal is of twofold interest to the Medical Profession. Firstly, the Hexachlorophene content ensures true germicidal properties, and the regular use of this toilet soap materially assists in the treatment and control of various skin infections as well as destroying bacteria which ferment perspiration

Secondly, as a soap for toilet purposes in surgeries, hospitals, etc., its qualities are admirable. The colourless, odourless, non-irritant and non-toxic properties of Hexachlorophene contained in Cidal, and its unique retention on the skin, ensures an exceptional degree of hygiene and protection for those engaged in medicine.

Please write for a sample of Cidal, and descriptive literature.

A Product of

J. BIBBY & SONS LTD. LIVERPOOL 3

A new formulation of 'Cetavlon'—

the quaternary ammonium compound which is already well known to the medical profession as a bactericide and detergent.

'CETAVLEX' CREAM, containing 0.5% 'Cetavlon' (Cetrimide B.P.) is a most useful antiseptic application for controlling infection in wounds and burns and for treating many skin infections. It may be used with advantage in the preliminary treatment of wounds of all kinds, and is an excellent first-aid dressing for eliminating infective bacteria and thus facilitating healing. As an antiseptic application to the hands prior to surgery or when dressing wounds, etc., the Cream forms an additional safeguard.

'Cetavlex' Cream will be found invaluable in everyday practice in hospitals, in the surgery, factory, or in the patient's home.

VICK
VAPOUR-RUB

Vick Vapour-Rub is a simple treatment, easy to apply. Rubbed on chest, throat and back, it acts in 2 ways to bring relief:—

1. AS AN INHALANT,

its soothing volatile ingredients are released by the body's warmth and inhaled to cold-irritated upper breathing passages.

2. AS A RUBEFACIENT,

it has a mild warming action on the surface of chest and back.

**CHEMOTHERAPY OF
TUBERCULOSIS****CALCIUM
Para-AMINOSALICYLATE GRANULATE**

*For
Reliable Therapeutic Performance*

'AMINACYL' CALCIUM P.A.S. GRANULATE, a highly concentrated form, contains about 85% anhydrous Calcium p-aminosalicylate, equivalent to 75% free acid P.A.S. and 9.8% calcium. Its superiority in the chemotherapeutic treatment of tuberculosis is characterized by its reliability to provide—

EFFECTIVE BACTERIOSTASIS. There is authoritative evidence that blood level curves obtained with 'Aminacyl' Granulate compare most favourably with those obtained with other forms.

ENTIRE ACCEPTABILITY. 'Aminacyl' Granulate is completely devoid of unpleasant taste; it is sialoresistant-coated.

HIGH TOLERABILITY. Liability to toxic symptoms is probably lower with 'Aminacyl' Granulate than with sodium salts; in particular, the possibility of serious blood potassium deficiency resulting from sodium P.A.S. is eliminated by employing the calcium salt.

PRESENTATION: Package for one week: 100gm. Package for one month: 400gm. Dispensing Package: 2,000gm.

A dosage measure (capacity 2gm. approx.) supplied gratis with each package.

'Aminacyl' Calcium P.A.S. is also available in the form of Dragees (0.395 gm.) in bottles of 250 and 1,000; and as bulk powder.

The problem was

to provide soluble aspirin in stable tablet form

Clinical sample and literature supplied on application. Solprin is not advertised to the public and is available only on prescription. (U.K. and Northern Ireland only.) It is not subject to Purchase Tax, and when prescribed costs actually less than 1d. for three tablets.

Aspirin is acidic, sparingly soluble, and for many subjects a gastric irritant. By contrast, its calcium salt is neutral, soluble and bland. Unfortunately, however, calcium aspirin as ordinarily presented is unstable, and thus sooner or later becomes contaminated with the breakdown products, acetic and salicylic acids. In 'Solprin'

the problem of providing calcium aspirin in a substantially neutral, stable and palatable form has been solved. Extensive clinical trials show that Solprin in large dosage and over prolonged periods, can be tolerated without the development of gastric and systemic disturbances, except in cases of extreme hypersensitivity.

SOLPRIN
REGD.

Stable, soluble, palatable calcium aspirin

BRITISH MEDICAL JOURNAL

LONDON SATURDAY FEBRUARY 9 1952

CARCINOMA OF THE STOMACH

BY

B. F. SWYNNERTON, D.M., M.R.C.P.

Late Senior Medical Registrar, Radcliffe Infirmary, Oxford

AND

S. C. TRUELOVE, M.D., M.R.C.P.

Assistant Physician in the Nuffield Department of Clinical Medicine, Oxford

Carcinoma of the stomach is one of the commonest neoplasms, and in 1949 accounted for the death of 8,096 men and 6,157 women (Registrar-General, 1951). It carries a bad prognosis, but examination of the literature reveals considerable discrepancies from one medical centre to another. We have therefore reviewed the experience of the Radcliffe Infirmary, which is well suited to this form of clinical study. Not only has it an efficient records department and a high standard of note-taking, but also, except in a few special branches of medicine, it functions as a community hospital and its patients are representative of the major illnesses in the area.

We have studied the case notes of all in-patients who were diagnosed as suffering from gastric carcinoma during the period 1938-49 inclusive, and have followed their progress. With the help of Miss Eva Spitz, almoner to the Nuffield Department of Clinical Medicine, and by making use of various sources of information—patients, relatives, friends, family doctors, food offices, and registrars of births and deaths—we have obtained satisfactory follow-up data in every case. The length of follow-up varies from 1 to 13 years.

Age and Sex.—Nearly twice as many men as women were admitted with the disease. In both sexes the peak case incidence occurs in the sixties, which is somewhat later than is given by many writers. From Table I, which sets out the distribution of cases by age and sex, it will be seen that gastric carcinoma is uncommon below the age of 30. Relatively more of the men develop the disease below the age of 60 (49% of the men, as opposed to 39% of the women). However, the difference is only at the borderline of statistical significance, so that it is of doubtful importance, particularly as the general

population contains a preponderance of women in the over-60 age groups.

Length of History.—The time between the onset of symptoms and admission to hospital varies greatly. Of every 100 patients, 46 were admitted within six months of their first symptoms, 36 between six months and two years, and 18 more than two years after. There was no difference between men and women. If age is taken into account, it is found that a significantly higher proportion of the patients over 60 reach hospital within six months of their first symptoms (Table II). We think

TABLE II

Age	No. of Patients	No. with History Less than 6 Months	%	Difference and Standard Error of Difference
Under 60	169	63	37.3	} 15.1 ± 5.1
Over 60	201	106	52.4	

that this is most probably due to the fairly wide recognition that dyspeptic symptoms in elderly patients are likely to be caused by malignant disease, so that they are investigated early.

Site of Lesion.—The precise site of the lesion was unknown in 34 patients, but in the remaining 341 it was as follows: pyloric end, 198 (58.1%); body, 73 (21.4%); cardiac end, 41 (12%); diffuse infiltrating, 29 (8.5%).

Age and sex have little influence on the site of the lesion. The only significant difference found was a higher incidence of the diffuse infiltrating form among the younger age groups; this occurred in 14% of the under-60 age group, as against 3.8% of older patients. Here we are dealing with a more invasive type of the disease rather than with its site, so that this difference is probably an example of the general finding that carcinoma is less invasive in elderly people.

Symptomatology

For early diagnosis a knowledge of symptomatology is of the utmost importance. The first symptom is one which deserves attention, and Table III shows a rough grouping of such symptoms in 371 patients in relation to the site of the neoplasm. (In the remaining four, carcinoma of the stomach was found at necropsy, the patients having been

TABLE I.—Case Distribution by Age and Sex

Age Group	Male		Female		Totals	
	No.	%	No.	%	No.	%
Under 30	4	1.7	3	2.1	7	1.9
30-39	9	3.9	9	6.3	18	4.8
40-49	44	18.9	16	11.3	60	16.0
50-59	57	24.5	27	19.0	84	22.4
60-69	85	36.5	59	41.5	144	38.4
70 and over	34	14.6	28	19.7	62	16.5
	233	100	142	100	375	100

admitted for some other condition.) It will be seen that in more than four out of every five patients the first symptom is one related to the gastro-intestinal tract. There is some indication that neoplasms of the fundal end of the stomach are more likely than others to present with constitutional symptoms (anaemia, weakness, lassitude, fever), but the difference is not striking.

TABLE III.—First Symptoms in Relation to Site

First Symptoms	Pyloric		Body		Cardiac		Diffuse		Un-known		Totals	
	No. of Pts.	%	No. of Pts.	%	No. of Pts.	%	No. of Pts.	%	No. of Pts.	%	No. of Pts.	%
Symptoms relating to G.I. tract	174	88.8	58	80.6	29	70.7	24	82.8	25	75.8	310	83.6
Constitutional	18	9.2	12	16.7	11	26.8	3	10.3	7	21.2	51	13.7
Due to secondaries	4	2.0	2	2.8	1	2.4	2	6.9	1	3.0	10	2.7
	196	100	72	100	41	100	29	100	33	100	371	100

Note: Four patients with no symptoms are excluded.

Of the 310 patients with symptoms classified as relating to the gastro-intestinal tract, 219 first complained of "indigestion." Less common first symptoms were vomiting (31 patients), constipation or diarrhoea (13), anorexia (11), lower abdominal pain (10), dysphagia (9), abdominal swelling (5), haematemesis or melaena (5), a palpable lump (3), perforation (3), and hiccup (1). Although a majority of patients present with "indigestion," this is extremely variable in its form, and includes slight epigastric discomfort or belching, epigastric pain related to meals, and continuous epigastric pain.

We have attempted to analyse the symptoms in more detail, particularly with respect to the dyspeptic group. Table IV shows in relation to the site of the lesion the main varieties of dyspepsia which occurred early in the patients' history, although they were not in all cases the first symptoms.

TABLE IV.—Analysis of Early Dyspeptic Symptoms (251 Patients)

	Pyloric	Body	Cardiac	Diffuse	Totals
Mild*	36	4	8	5	53 (21.1%)
Ulcer type	42	14	4	6	66 (26.3%)
Pain after meals unrelieved by food and alkalis	26	7	3	1	37 (14.7%)
Long history of vague dyspepsia	16	6	4	3	29 (11.6%)
Continuous pain	21	19	4	3	47 (18.7%)
Pyloric stenosis	16	1	0	2	19 (7.6%)
	157	51	23	20	251 (100%)

* Mild symptoms include vague abdominal discomfort, fullness, belching, regurgitation, etc.

It will be seen that any type of dyspepsia can occur with neoplasms in any situation within the stomach. Symptoms suggesting pyloric stenosis occur mainly in lesions of the pyloric end and, less commonly, in diffuse infiltrating lesions. Continuous epigastric pain was experienced more frequently with carcinoma of the body than with lesions elsewhere. But, with the exception of the symptoms of pyloric stenosis, the most striking fact about the findings is that the site exerts little influence on the type of dyspepsia met with early in the course of the disease. It is also worth noting that, although carcinoma of the pyloric end is very common, the picture of pyloric stenosis is found in only 10% of such cases during the early stages.

Dyspeptic symptoms are experienced by a larger number of patients at the time of their admission to hospital, and continuous epigastric pain and the pyloric stenosis syndrome are more commonly found, between them accounting for 50% of the dyspeptic symptoms. In other words, between the early stage of the disease and admission to hospital the

symptomatology has changed towards the conventional "textbook picture" of carcinoma of the stomach.

Dysphagia.—This is a fairly common symptom in carcinoma of the cardiac end of the stomach, and may occasionally occur with neoplasms in other situations. As an early symptom it was present in nine patients, eight of whom had a fundal neoplasm and one a carcinoma of the body. By the time of admission to hospital 13 of the 41 patients with fundal carcinomata and 4 patients with lesions elsewhere had dysphagia.

Haematemesis and Melaena.—Although rarely found as an initial symptom, frank bleeding from the gastro-intestinal tract is common in carcinoma of the stomach. Recognizable haematemesis or melaena occurred in 77 of the 375 patients, and were prominent symptoms in 28. It is sometimes held (for example, Harnett, 1947) that bleeding occurs most commonly from growths at the cardiac end. In the present series the site of the lesion appeared to have little influence on the liability to bleed.

Perforation.—There were eight cases of perforation, of which two occurred in hospital while the patients were under investigation. In three patients the perforation was the first symptom, and there was no previous history of dyspepsia. During the same period (1938-49) approximately 563 cases of perforation of the stomach or duodenum from all causes were treated in the Radcliffe Infirmary. Doll (1950) found 17 cases of perforated gastric carcinoma in a series of 452 gastric and duodenal perforations. He found that in a proportion of cases the diagnosis at operation was that of a simple lesion, and that the diagnosis of carcinoma was made only subsequently. Had all cases of perforation at the Radcliffe Infirmary been followed up in a similar manner it might well be that more cases of carcinoma would have been found.

Physical Examination.

The physical examination may or may not be helpful in establishing the diagnosis of gastric carcinoma. The presence of an epigastric mass is of course strongly in its favour. In this series a mass was palpated on admission to hospital in nearly half the patients. A mass was found in 159 (54.1%) of the 294 patients with a "positive history," and in 19 (23.5%) of 81 patients with negative histories. (We defined a "positive history" as one which to us was suggestive of gastric neoplasm.)

It may be that this difference is mainly due to the more thorough abdominal examination of patients with histories suggestive of gastric neoplasm, but another explanation may also be valid—namely, that many gastric carcinomata may not give rise to dyspeptic symptoms until they are large enough to be palpated.

Associated Conditions

Chronic Gastric Ulcer.—In 26 of the 375 patients there was some evidence that the neoplasm might have arisen from a simple gastric ulcer. The relationship of ulcer to carcinoma is a controversial one, and we have discussed the evidence derived from the present series in a separate paper (Swynnerton and Truelove, 1951). For the moment it must serve to remark that we believe a minority only of these 26 patients were truly examples of "ulcer-cancer."

Pernicious Anaemia.—While some workers, such as Kaplan and Rigler (1945, 1947), believe that patients with pernicious anaemia are unduly prone to develop carcinoma of the stomach, others, such as Wilkinson (1945), disagree with this view. Among the 375 patients of the present series, four had a history of pernicious anaemia which clearly antedated the development of their carcinoma. Pernicious anaemia is an uncommon condition, so that these results, though by no means conclusive in themselves, conform with the findings of Kaplan and Rigler.

Double Carcinoma.—Carcinoma of the stomach was not the only malignant neoplasm experienced by five of the

patients, if we include their past histories. The relevant details of the other neoplasms were:

(1) Man aged 57: Papilliferous adenocarcinoma of kidney, removed three years previously. (2) Man aged 60: Adenocarcinoma, Broders's grade II of descending colon, removed five years previously. (3) Man aged 67: Polypoid carcinoma of recto-sigmoid junction concurrently. (4) Man aged 66: Squamous-cell carcinoma of tongue, concurrently. (5) Woman aged 61: Squamous-cell carcinoma of left nipple (Paget's disease), concurrently.

It has been stated that the incidence of multiple primary carcinoma is higher than would be accounted for by chance. Barrett, Miller, and Fessenmeyer (1949) quote 14 authorities whose figures vary from 0.3 to 6.8%, with an average incidence of 1.8% of all cancer cases.

Investigations,

Radiology: Barium Meal

A barium meal is the most accurate single investigation in the diagnosis of carcinoma of the stomach. Among the present series, 297 patients were investigated by this method, and the radiologists reported a gastric abnormality in 90.5% of these at the first examination. If we include repeat examinations the figure rises to 95.6%. In 7.4% of cases, although an abnormality was detected, the radiologist did not interpret the findings as suggesting carcinoma. This should not detract from the value of the method, because it is the duty of the clinician to make the diagnosis; evidently in 83.1% the radiologist was able to state after the first examination that the lesion was probably malignant.

Fractional Test Meal

The fractional test meal is widely used as a diagnostic measure. It was performed in 183 patients. Table V shows the results according to the following arbitrary classifications: (1) achlorhydria; (2) hypochlorhydria—with peak values less than 20 ml. N/10 HCl per 100 ml.; (3) normal—20–60 ml.; and (4) hyperchlorhydria—over 60 ml.

It will be seen that achlorhydria is a common finding, but that one in every four patients has normal or unusually acid gastric secretions. The findings are similar in the two sexes.

It is interesting to compare these results with those obtained in simple gastric ulcer and duodenal ulcer. The results for the latter were obtained by selecting in sequence from the Radcliffe Infirmary records 100 cases in which the diagnosis appeared certain (Table V). The comparison

TABLE V.—Results of Fractional Test Meal in Gastric Carcinoma, Simple Gastric Ulcer, and Duodenal Ulcer

	Gastric Carcinoma (183 Cases)	G.U. (100 Cases)	D.U. (100 Cases)
Achlorhydria ..	58.5%	11%	2%
Hypochlorhydria ..	15.3%	14%	0%
Normal ..	21.3%	56%	55%
Hyperchlorhydria ..	4.9%	19%	43%

shows that, even on a single test meal, the occurrence of achlorhydria or hypochlorhydria is rare in duodenal ulcer. The practical importance of this finding arises from the circumstance that juxta-pyloric lesions may be impossible to locate with exactitude on radiological grounds in the duodenum or pyloric antrum.

By contrast, achlorhydria or hypochlorhydria is found in one of four patients with simple gastric ulcer. In distinguishing between simple gastric ulcer and carcinoma it is clear that the fractional test meal has only limited value: on the one hand, the occurrence of achlorhydria would weigh in favour of carcinoma; on the other, and more important, the finding of normal or hyperchlorhydric gastric secretion is no bar to the diagnosis of carcinoma. This latter conclusion is well known to workers in the field of gastro-enterology but is not yet sufficiently appreciated by the medical profession as a whole.

Occult Blood

Stools were examined for occult blood in 157 patients. Occult blood was present in large or moderate amounts in 84%, and half the remainder showed a trace. The chief value of this test appears to be the focusing of attention on the gastro-intestinal tract in cases of anaemia and others without dyspeptic symptoms.

Gastroscopy

Gastroscopy was normally carried out only when there was some doubt about the diagnosis. In the 33 patients so examined the results were as follows: right diagnosis, 21; wrong diagnosis, 5; failed or unsatisfactory, 7.

Treatment and Prognosis

Table VI shows the prognosis for the whole series. It will be seen that the picture is a gloomy one. Four out of five patients are dead within a year of admission to hospital, and 19 out of 20 within five years. There is no appreciable difference between men and women.

TABLE VI.—Percentage Survival Rates of the Whole Series

Length of Follow-up	Totals		
	No.	No. Alive	% Alive
1 year ..	375	80	21.3
2 years ..	322	36	11.2
3 " ..	282	26	9.2
4 " ..	238	16	6.7
5 " ..	196	11	5.6
6 " ..	173	8	4.6
7 " ..	151	5	3.3

More useful information arises from constructing separate survival curves for the groups treated by radical surgery and all others (Table VII and Fig. 1).

TABLE VII.—Prognosis in Resected Group Compared with that of Remainder

6 " ..	38	8	21.1	135	0	0.0

FIG. 1.—Percentage survival rates in gastric carcinoma.

Although the two groups are not strictly comparable in that patients treated by resection are those in whom no widespread metastasis was found, the difference between them is so striking that it is fair to conclude that radical surgery offers the only chance of prolonged survival.

The non-resected group includes 46 patients who were treated by palliative operation and 76 who were explored and for whom nothing was done. Their survival rates do not differ greatly from patients receiving no treatment. There is some indication that palliative surgery may prolong life; but our numbers are small, and it seems likely that palliative surgery has no great influence on expectation of life, although it may be called for to relieve symptoms.

The high rate of fatality during the first year after resection is partly due to a considerable fatality rate in the immediate post-operative period (22%). It is evident that this must be included in any judgment of the value of surgery. Nevertheless, it is of some value to show the survival rates of those patients who survive operation (Table VIII), for two reasons:

(a) Many writers base their conclusions on the survival rates of patients who live beyond the immediate operation period. Although we regard this as an erroneous method of presenting the results of surgery, particularly when it is used in isolation, no comparison with their results is possible unless similar data are presented.

(b) It is reasonable to suppose that, with improved pre-operative and post-operative care arising from such circumstances as the widespread use of antibiotics, developments in anaesthesia, and the application of biochemical knowledge, the immediate post-operative fatality may decline and the prognosis for the resected group as a whole may in future approximate to that of the patients who survive operation.

TABLE VIII.—Prognosis in Resected Group, Excluding Post-operative Deaths

4 "	46	14	30.4
5 "	34	10	29.4

Resectability

Altogether, 236 patients were submitted to laparotomy—an operation rate of 63%. It is, however, unfortunate that only 114 of the 375 patients (30%) were judged suitable for resection. During the time covered by our study the proportion of patients treated by resection increased from 22.7% in the first half of the time to 35.7% in the second. Table IX shows that an increased proportion of all age groups were treated by resection during the second period, and the most striking difference is shown in the patients aged 70 and over. We are unable to assess with any precision the extent to which this increased resectability rate was due to earlier diagnosis or to bolder surgery. Whether the recent increased resection rate will be justified by long-term results must await later study.

TABLE IX.—Percentage of Patients Treated by Radical Resection in Relation to (a) Age, (b) Period of Time

Totals ..	151	34	22.5	224	80	35.7

Length of History and Prognosis

It is axiomatic in clinical medicine that the sooner a diagnosis of malignant disease is made the more likely is surgical resection to effect a cure. We were therefore interested to break down the "resected group" into subgroups according to the length of history (Table X, Fig. 2). Although the numbers are small the differences between the three groups are quite definite, and prognosis appears to improve with increasing length of history. This is well shown by considering three-year survivals only, as in Table XI, where the differences between the three groups are highly significant.

This result is at first sight surprising, because it might be taken to indicate that early diagnosis is disadvantageous. There are several more probable explanations of this seeming paradox, such as: (a) The patients with long histories may be examples of slowly growing malignant disease, in which secondary spread is slow. (b) The patients with long histories may contain a high proportion of the so-called "ulcer-cancers" with a good prognosis. (c) The patients with long histories may have been misdiagnosed, through simple peptic ulcers having been mistaken for malignant disease.

FIG. 2.—Percentage survival rates in relation to length of history of patients treated by resection.

TABLE X.—Survival Data in Relation to Length of History

Length of Follow-up	Length of History					
	Under 6 Months		6 Months-2 Years		Over 2 Years	
	No.	No. Alive	No.	No. Alive	No.	No. Alive
1 year	47	17	42	24	25	19
2 years	34	5	29	13	24	14
3 "	26	2	22	8	24	13
4 "	23	1	14	3	20	10
5 "	20	1	10	3	13	6

TABLE XI.—Three-year Survival Figures

Length of History	No.	No. Alive	%
Less than 6 months ..	26	2	7.7
6 months to 2 years ..	22	8	36.4
Over 2 years ..	24	13	54.2

$$\chi^2 = 12.683. \quad n = 2. \quad P < 0.01.$$

We were therefore driven to re-examine our data in the light of these and other possibilities. So far as misdiagnosis is concerned, further scrutiny of our data did not suggest that the criteria governing diagnosis were different in the various subgroups. With respect to the possibility that the patients with long histories were examples of "ulcer-cancers," it is worth mentioning that there were 10 patients in the resected group in whom there was some evidence that the carcinoma might have arisen in a simple ulcer. In one of these the carcinoma was found at operation to be quite distinct from a chronic ulcer, and a number of the remaining nine may have been examples of ulceration in a carcinoma for reasons which we have presented separately. However, even if we assume that all the nine patients were true examples of "ulcer-cancer" this circumstance does not account for the relationship between length of history and

prognosis, because if these nine patients are excluded the findings are unaltered (results not shown).

It will be recalled that in an earlier section it was shown that a significantly higher proportion of patients over 60 years of age were admitted with a short history. It is therefore possible that the poor prognosis of the patients with a short history might be due to their being unduly loaded with elderly patients, who are bad operative risks. That the elderly are less able to withstand operation is shown by the following figures for the group treated by resection:

Age	No.	Post-operative Deaths
Under 60	60	10 (16.7%)
Over 60	54	15 (27.8%)

We have therefore subdivided our data with respect to length of history and three-year survival rates to show what happens in two main age groups (Table XII).

TABLE XII

Age of Patient	Length of History							
	Under 6 Mths.		6 Mths. to 2 Yrs.		Over 2 Yrs.		Totals	
	No.	No. Surviving	No.	No. Surviving	No.	No. Surviving	No.	No. Surviving
Under 60 ..	8	1	14	7	17	7	39	15
Over 60 ..	18	1	8	1	7	6	33	8

Although the numbers are small they are consistent, and they indicate that the length of history is a more important prognostic sign than the age of the patient. Indeed, if we exclude post-operative deaths we are left with the following figures for three-year survivals:

Age	No. Surviving Operation	No. Surviving 3 Years
Under 60	35	15 (42.9%)
Over 60	24	8 (33.3%)

It will be seen that, although the older group of patients had a worse prognosis than the younger, the difference is not great.

The further possibility existed that the length of history might vary according to the site of the carcinoma within the stomach, and thus explain the association between length of history and prognosis. We have therefore analysed our data with respect to both length of history and site of lesion. The pyloric subgroup, which is the only sizable collection of patients, shows a marked association between the length of history and prognosis, which agrees with our finding for the resected group as a whole. The numbers in the other subgroups are small, but those for body of stomach are sufficient to show the same trend. We are therefore consistently finding that the longer the history the better the prognosis among the resected group. It is clear that the age distribution of the patients, the site of the lesion, and the possibility of "ulcer-cancer" do not serve to explain the good prognosis of patients with a long history in the resected group, and we believe that this association is due to the occurrence of slow-growing carcinomata.

We might therefore expect a close association between the length of history and the grade of malignancy as judged by Broders's classification. The figures in Table XIII show no such correlation.

TABLE XIII

Length of History	Broders's Classification	
	I and II	III and IV
Under 6 months	17	30
6 months-2 years	13	28
Over 2 years	9	17

Likewise, if the three-year survivals are related to both length of history and Broders's classification it is found that the length of history is much the more important factor in determining prognosis (results not shown).

Discussion

An outstanding finding in the present study is the marked prognostic significance of length of history among the patients treated by surgical resection. The longer the history the better the prognosis in this group of patients. For reasons which we have given, we believe that this finding is due to the likelihood that the neoplasm is a slow-growing one if symptoms have lasted for more than two years and the growth is still suitable for resection.

We are not the first to uncover this association, for several workers from the Mayo Clinic have come to the same conclusion. For example, Balfour (1937) reported that patients with a history of less than six months who survived resection had a five-year survival rate of 25% as opposed to one of 35% among patients with a history of more than one year, and similar findings were recorded in the later study by Walters, Gray, and Priestley (1942). Our findings are in the same direction, but the prognostic influence of length of history seems to be more pronounced. To some extent this may be due to the smaller numbers with which we have dealt.

This finding should not be taken to indicate that early diagnosis is of little consequence. On the contrary, we believe that every effort should be made to shorten the time between onset of symptoms and the making of the diagnosis. It is important to bear in mind that the improved prognosis with greater length of history applies only to the group of patients treated by resection. Our main concern must be with the prognosis of the whole group of patients with carcinoma of the stomach. Most patients are not suitable for resection by the time they are admitted to hospital, and when considering the good prognosis of the small group with a long history still fit to have a resection we must bear in mind that they are the residue of a much larger group, the majority of whom have died or have become unfit for operation before that amount of time has elapsed.

Early diagnosis is not easy. The symptoms are extremely variable, although it is fortunate that the great majority of patients have early symptoms referable to their gastro-intestinal tract, with some form of "indigestion" as the commonest manifestation. No reliance can be placed upon the type of indigestion, and physical examination is useless for early diagnosis. Undoubtedly, a barium meal is the surest way of demonstrating the presence of a neoplasm, and ideally it should be carried out as a routine in all patients over 40 who develop indigestion. (We find ourselves in sympathy with Jennings (1947), who, writing at a time of milk-rationing, remarked that "... the effect of demanding an x-ray diagnosis before signing a certificate for extra milk should lead to earlier cases being discovered.") If the barium meal is negative and the indigestion persists, further barium meals should be carried out. Gastroscopy may be useful as an ancillary to the barium meal, particularly in cases with some doubt about the diagnosis.

Summary

During the 12-year period 1938-49 inclusive, 375 patients with carcinoma of the stomach were treated in the Radcliffe Infirmary. Adequate follow-up data have been obtained for all of them.

Nearly twice as many men as women were admitted, and in each sex the peak case incidence occurred in the sixties.

There was great variation in the length of history before admission to hospital. Nearly half were admitted within six months of their first symptom, while at the other extreme nearly one in five had symptoms lasting for more than two years.

The commonest site of neoplasm was the pre-pyloric region and the least common the fundus.

More than four out of every five patients began their illness with symptoms referable to the gastro-intestinal tract, the majority suffering from some form of "indigestion." The type of indigestion was extremely variable.

An epigastric mass was felt in about half the patients by the time of admission to hospital.

A barium meal is the most accurate single diagnostic procedure. In nine out of ten patients the radiologists reported a gastric abnormality at the first examination, and in more than four out of five correctly interpreted the findings.

Achlorhydria was a common finding, independent of the age of the patient or the site of the neoplasm. On the other hand, normal or unusually acid secretions were found in one out of four patients, so that such findings should not be regarded as any bar to the diagnosis of gastric carcinoma.

Most patients had occult blood in their stools.

Laparotomy was carried out in 63% of the patients and resection of the growth in 114 (30% of the total 375). An increased proportion in all age groups were treated by resection during the second half of the period covered by this study.

Resection offers the only hope of prolonged life. For example, nearly a quarter of the resected group were alive after five years, compared with less than 1% of the remainder.

Among the resected group, the outstanding factor influencing prognosis was the length of history. Somewhat unexpectedly, the prognosis was found to improve with increasing length of history. The age distribution of the patients, the site of the lesion, and the possibility of "ulcer-cancers" do not explain this finding, and we conclude that it is due to the occurrence of slow-growing carcinomata.

We wish to thank the physicians and surgeons of the Radcliffe Infirmary for permission to make this study. We are grateful to the records officer, Miss Coombs, and her staff for their assistance; and to Miss Eva Spitz for her help in completing the follow-up of patients. Dr A. H. T. Robb-Smith and Dr. Hugh Cowdell very kindly confirmed the histological classification in a number of cases. Clerical expenses were met by a grant from the Division of Medicine, Radcliffe Infirmary.

The Ministry of Transport has just issued a notice (M.358) to shipowners and masters on the cleansing of fresh-water tanks and filters, and recommending the avoidance of sea water in washing up and cooking, especially when near a coast or in harbour. Filters do not guarantee bacteriological sterility, and need cleaning at least once a month.

A SURVEY OF 17,301 PRESCRIPTIONS ON FORM E.C.10

BY

D. M. DUNLOP, M.D., F.R.C.P.

Assisted by T. L. HENDERSON, M.B., Ch.B., M.R.C.P.Ed.,
 and R. S. INCH, M.B., Ch.B., M.R.C.P.Ed.

(From the Department of Therapeutics, University of Edinburgh, and the Clinical Laboratory, Royal Infirmary, Edinburgh)

The relative frequency with which different drugs are prescribed and the form in which they are dispensed is always a matter of interest to a department of therapeutics. In consequence the offer of a large number of representative prescriptions for analysis was gladly accepted. These forms (E.C.10) had already been passed by the Pricing Bureau, and, so that the investigation should be entirely anonymous, the prescriber's name had been deleted before the prescriptions were submitted for analysis.

Material and Method

The prescriptions surveyed covered the month of September, 1949. They had previously been divided by the Prescribing Committee as coming from three main areas in England, the distinction between the areas being based on supposed social or financial differences. The areas were classified as follows: (1) prosperous residential; (2) industrial; and (3) mixed suburban. Each area included four to six districts of dissimilar geographic and administrative distribution. For example, the industrial area represented industrial districts in the North, Midlands, and West of England. The choice of areas and the districts which they included were arranged by the Central Prescribing Committee in such a way as to ensure the widest possible scatter.

In each district the prescriptions came from one chemist only (four to six chemists per area). In consequence the number of doctors whose prescriptions are represented in this survey is smaller than we could have wished. As has been stated, the prescriptions were all anonymous, so that the exact number of doctors involved is impossible of computation, but is certainly not fewer than 140.

The number of E.C.10 forms submitted for analysis was 11,435, but as there were often several prescriptions on a single form the total number studied was 17,301. No practitioners' orders for stocks (Form E.C.10A) were submitted, and the survey gives no indication of the drugs dispensed personally by doctors.

All the information given on each form was tabulated on specially prepared sheets, each sheet containing 14 main headings and 45 subheadings. The information so derived was then transferred to punch cards. The prescriptions from each area were kept separate so as to allow of a comparison being made between them. Certain drugs which were only rarely prescribed were tabulated on a separate sheet and were not transferred to punch cards. This latter group comprised 412 items, representing 18 different preparations.

Results: (1) Proprietary or Non-Proprietary

Each prescription was classified as representing a proprietary or non-proprietary preparation. When the prescription contained both it was classified according to the

predominating preparation. This was not always an easy choice to make, but as the number of such prescriptions was very small any resulting error is insignificant. It will be seen from Table I that there was a considerable variation

TABLE I.—Absolute Figures and Percentages

	Areas			Total
	Residential	Industrial	Mixed Suburban	
Proprietary	1,455 (27%)	1,323 (21%)	790 (14%)	3,568 (21%)
Non-proprietary	3,821 (73%)	4,985 (79%)	4,927 (86%)	13,733 (79%)

in the proportion of proprietary and non-proprietary preparations prescribed in the different areas. As might be expected, a much higher proportion of elegant and expensive proprietary preparations were prescribed in the prosperous residential than in the industrial area. A higher proportion of such prescriptions, however, occurred in the industrial than in the mixed suburban area. In consequence it is probable that the variations in this respect are due more to the prescribing habits of the doctors concerned than to the social groups catered for—a situation which would almost certainly have been very different had the analysis been made prior to the National Health Service Act. That 21% of all prescriptions written were for proprietary drugs would seem to be excessive, and there is every reason to believe that this percentage has risen considerably in the past year.

(2) Type of Preparation

Each preparation was classified as belonging to one of ten types. The frequency with which these types were prescribed and their relative frequency in the different areas are shown in Table II.

TABLE II

	Areas			Total
	Residential	Industrial	Mixed Suburban	
Mixture	1,659 (31%)	2,367 (38%)	2,206 (38%)	6,232 (36%)

Ear, eye, and nose (topical)	210 (4%)	253 (4%)	225 (4%)	688 (4%)
Dressings/appliances	428 (8%)	589 (9%)	631 (11%)	1,648 (9%)
Injectables	79 (2%)	118 (2%)	48 (1%)	245 (1%)
Suppositories/pessaries ..	37 (1%)	35 (1%)	17 (1%)	89 (1%)

It will be seen that *mixtures and tablets* accounted for 68% of all prescriptions. As in the case of the proprietary and non-proprietary preparations, and for the same reason, the variation in the proportion of mixtures and tablets prescribed in the three areas is probably due to the preference of the individual doctors concerned rather than to the social groups catered for. The prescriptions for preparations other than tablets or mixtures showed a remarkable similarity of distribution throughout the three areas.

Except in the case of children, tablets are usually not only a more accurate but a more convenient form in which to take a medicine. In addition they are generally cheaper than mixtures and the dispensing fee for them is smaller. It is thus most desirable that, whenever possible, tablets should be prescribed in preference to the corresponding mixture.

Powders comprised only 1% of the total prescriptions. Stomach powders were particularly neglected in favour of the more expensive and cumbersome mixtures. As alkaline powders are less expensive, can be prescribed in larger bulk, and are also more conveniently carried than the corresponding mixture, the powder should generally be prescribed in preference to the mixture.

Dressings and appliances accounted for 9% of the total. Many of these items were expensive, and lint and cotton-wool were often ordered in enormous quantities.

Injectables formed only 1% of the total, which suggests that the parenteral administration of drugs—so unnecessarily popular on the Continent—is not a feature of English medical practice. It has to be remembered, however, that injections have usually to be given by the doctor himself, and will thus in some cases have been ordered on the stock E.C.10A form and not on Form E.C.10.

(3) Actual Drugs or Groups of Drugs

Table III indicates the actual preparations prescribed. Their arrangement is in descending order of frequency, the figures giving the actual number of times they were prescribed.

TABLE III

Order	Group	Preparation	Times Prescribed	Group Total
1	Hypnotics and sedatives	{ Barbiturates Bromides	1,636 1,007	2,643
2	Stomachics ..	—	—	
3	Tonics ..	—	—	1,678

18	Strong analgesics	{ Morphine Diamorphine Pethidine, physe- tone, etc.	57 37 62	156

It is a significant commentary on present-day conditions that hypnotics and sedatives should form far the largest single group (15%) of all drugs prescribed. Barbiturates comprised 9.4% and bromides 5.8% of this total. Bearing in mind the numerous unpleasant side-effects of bromides, their continued popularity is surprising, as there is little which bromides can do that phenobarbitone cannot do better. Further, bromides were often prescribed in 10-gr. or 15-gr. (0.65- or 1-g.) doses, not as a general sedative but as a hypnotic to be taken only at night. Bromides have to reach a considerable concentration in the blood before there is a sufficient replacement of chlorine ion to exert any depressant action on the central nervous system. It is therefore doubtful whether such small single doses are any more effective as hypnotics than a draught of salty water, apart from the psychological effect which may be produced by taking such a medicine. Chloral hydrate was only very occasionally incorporated in the bromide mixture. It is strange that this well-tried and valuable hypnotic, which is so peculiarly suitable for children, should be used so seldom.

It was prescribed by itself on only one occasion. Paraldehyde did not appear on a single prescription. Apart from phenobarbitone, the barbiturates were almost invariably ordered under their proprietary names.

Under the heading "*stomachics*" were grouped alkalis, antacids, cholagogues, olive oil, etc. Such preparations formed the next largest group to sedatives, comprising just over 9% of all prescriptions.

Tonics included many elegant and complex recipes which are still manifestly popular, although they must generally be classed as placebos, the justification for which is a matter of considerable current controversy.

Thus sedatives, stomachics, and tonics together formed about one-third of all preparations issued. The conditions requiring the use of these medicines have something in common with each other, and the whole group, though perhaps to a less extent than the sedatives alone, gives an indication of the type of malady for which doctors are commonly consulted at the present time.

Antipyretics and mild analgesics appeared almost as often as stomachics—that is, 8.8:9.1%. The prescription of *mist. aspirin. B.P.C.* was very popular, as was *tab. codein. co. B.P.* and its proprietary equivalents. It is very probable that large quantities of such mild analgesics are bought by patients themselves.

Expectorant cough mixtures were prescribed more than twice as often as sedative cough mixtures, yet the value of expectorants is doubtful. It is supposed that 5 gr. (0.32 g.) of ammonium chloride three times a day will liquefy the bronchial secretions, yet 20 gr. (1.3 g.) three times a day is often employed to render the urine acid without the patient noticing any such expectorant effect. The frequent combination of expectorant and sedative cough mixtures as indicated in Table III would seem to demonstrate some therapeutic confusion.

About 40% of all *vitamins* prescribed were for proprietary preparations. Aneurin and vitamin-B complex made up almost half the total of vitamins issued. Vitamin C formed less than one-tenth of the total. Yet there is probably less justification for the widespread use in this country of aneurin, nicotinamide, and riboflavin than for ascorbic acid. It can be argued that people sometimes do not obtain enough fresh fruit and green vegetables in our long winters and so may run short of ascorbic acid in the spring. Aneurin is apparently used for every imaginable neurological condition in the mistaken belief that it has a beneficial effect on the neuritic pains encountered in this country. The prescribing of large doses of water-soluble vitamins has at least this safety-valve, that the body eliminates them rapidly; but imagination boggles at the thought of the pounds' worth of unwanted synthetic water-soluble vitamins that are now daily lost in human urine. Vitamin E was ordered the least often, but one prescription for this cost over £14 and many about £5. Such prescriptions justify the need to stress the cost of drugs in undergraduate and postgraduate teaching. It might also be made obligatory for manufacturing chemists to include prices in their advertisements. Multiple-vitamin preparations were often prescribed, and are undesirable. They lull the physician into a false sense of security that he has done all that is necessary for the proper nutrition of his patient; they vary widely in composition and may lack the particular vitamin (perhaps not available in synthetic form) which might conceivably help the patient, and may thus create a state of vitamin imbalance by providing an excess of others.

Penicillin in all its forms accounted for about 4% of the total, but only 6.9% of this was for parenteral administration. About 30% of the prescriptions for penicillin were for oral preparations and over 40% for penicillin ointments. As has been suggested above, the seemingly small proportion of prescriptions for penicillin to be given by injection may be accounted for to some extent by the doctors giving it from their own stocks. The percentage of prescriptions for orally administered penicillin was surprisingly high, especially as

these orders for small doses were given before a high dosage of oral penicillin had been proved to be therapeutically effective.

It is surprising that *adrenaline* was prescribed so infrequently when asthma is so common. Doubtless adrenaline is often injected by the doctor himself from his own stocks, but it would seem from the figures that the habit of self-injection with adrenaline is not commonly taught to asthmatics.

A preparation of *iron* was included under this heading only if it contained amounts of iron approximating to the dose recommended in the *B.P.* Some of the favourite prescriptions for iron, strychnine, and phosphates contain very little available iron and were classed as tonics. Prescriptions for iron in adequate amounts comprised only 3.5% of the 17,301 items surveyed, and in over half of these it was prescribed as a mixture. In most cases it is preferable to give iron as a tablet, not only for the reasons already advanced regarding tablets and mixtures, but also because of greater palatability and the fact that ferrous sulphate in tablet form does not discolour the teeth. When the high incidence of iron-deficiency anaemia in this country is considered in comparison with the relative rarity of vitamin-deficiency states it is remarkable that iron should have been prescribed only 623 times in comparison with 739 prescriptions for vitamins. No doubt iron preparations are often dispensed at maternity and child-welfare clinics, and such issues do not appear on Form E.C.10, but the same can be said of vitamins.

The total of prescriptions for *laxatives* was smaller than anticipated, and strongly suggests that many people still buy their own laxatives.

Sulphonamides formed 3% of the total prescriptions, so that even in 1949 they were less frequently prescribed than preparations of penicillin. Of the prescriptions for sulphonamides 56% were for tablets, 12% for mixtures, and 10% for skin preparations. In view of the likelihood of evoking sensitivity reactions by the topical application of sulphonamides, this last figure is probably undesirably high.

Only 14% of the prescriptions for *cardiac glucosides* were for tincture of digitalis, which used to be the most popular way to prescribe the drug. It is all to the good that the tincture is gradually being replaced by the powdered leaf—which contains all that the foxglove has to offer—and by "digoxin." These latter preparations keep better than the tincture, and with them the dosage is more accurate. Quinidine did not appear on any prescription.

Diabetes is a common disease, while the megaloblastic anaemias are comparatively rare. Yet *liver* preparations were ordered 50 times, in comparison with only 68 prescriptions for *insulin*. This suggests that liver is often prescribed as a general tonic or for the treatment of anaemic patients other than those specifically requiring the haemopoietic factor. It is very doubtful whether the use of liver is ever indicated except in the treatment of the megaloblastic anaemias.

It will be seen that even two years ago *amphetamine* was becoming popular, and in this survey it was prescribed 218 times, which is half as often again as the prescriptions for ephedrine. It is probable that since 1949 its use has increased considerably. "Dexedrine" is included under this heading. It is very much more expensive than amphetamine, and it is doubtful whether it possesses any advantages over the latter.

Prescriptions for *diamorphine* (heroin) constituted about one-third of the orders for strong analgesics. In view of the great danger of habituation to this drug and the fact that in some countries its use is prohibited, the figure is a high one.

(4) Drugs Rarely Prescribed

It is fortunate that "shot-gun" preparations for iron with folic acid, liver, or hog's stomach, which are justifiable on no sound haematological basis, should not have been

TABLE IV

No. of Times Prescribed	Name of Drug
Under 60	Calcium
" 50	Iron with folic acid, or liver, or hog's stomach
" 40	Anthelmintics
" 30	{ Phenytoin
	{ "Methedrine" and nikethamide
	{ Cold vaccines
	{ Other vaccines
" 20	{ Mersalyl
	{ Ergot
	{ Ergotamine tartrate
	{ "Diparcol" and "trasentin"
7	"Pernivit"
3	"Priscol"
2	{ Thiouracil
	{ Stannoxyl
1	{ Antimalarial
	{ "Tridione"
	{ "Myocrisin"

prescribed more than 50 times, and that vaccines for the prevention of the common cold, for the use of which there can be little scientific justification, do not seem to have been popular.

Mersalyl is a valuable drug which was prescribed fewer than 20 times. It is, however, an example of a drug which the doctor often administers from his own stores. Nevertheless the number of times it appeared on these forms seems surprisingly low.

It also seems quite remarkable that *thiouracil* was prescribed only twice out of 17,301 prescriptions. In spite of the fact that it is often used under hospital supervision, it is generally the practitioner who writes the prescription for maintenance treatment. If this practice is general it can only be supposed that the conservative treatment of thyrotoxicosis with *thiouracil* is less common in England than might have been expected.

Conclusions

The study of a large number of prescriptions provokes certain reflections on the teaching of pharmacology and practical therapeutics in our medical schools. In some schools pharmacology is taught along with physiology as a preclinical subject. In others it is taught in the first clinical year, when the student has seen only a limited number of the disorders the treatment of which is discussed. Thereafter instruction in treatment is often limited to the last ten minutes of a medical clinic, and during the fifth and sixth years of his course the undergraduate often forgets the actions and uses of the drugs which he heard about while studying pharmacology. In consequence many young graduates go into practice with a very inadequate knowledge of applied pharmacology, and tend to rely more and more on the ingenious (sometimes very good, but sometimes very misleading) advertisements of the drug firms which cover his breakfast table. In the days when there were few potent or specific drugs this ignorance of applied pharmacology was of less importance. Nowadays when we are Jove-like in the therapeutic thunderbolts we can hurl—drugs potent for evil as well as for good—it is of paramount importance for us to be thoroughly conversant with the pharmacological tools of our trade. It is suggested, therefore, that a series of simple lectures in therapeutics by a practical physician interested in pharmacology should be given in the last clinical year of the medical course. It is a subject which lends itself to systematic lecturing, and is of more importance than the study of some of the more recondite specialties which at present overload the curriculum.

Courses in pharmacology in medical schools are now usually, and very properly, undertaken by academic scientific pharmacologists, who have revolted against the old-fashioned instruction in *materia medica* and in the compounding of elaborate prescriptions elegantly flavoured, meticulously bottled, and exquisitely labelled. They have realized that there are few occasions in practical therapeutics which demand the prescription of more than one drug in a bottle, tablet, or powder, plus the vehicle and flavouring agent. Perhaps, however, the pendulum has swung too far in the other direction and that inadequate instruction is now being given in the principles of correct simple prescribing. At a recent oral examination for one of the higher clinical diplomas five consecutive candidates were quite unable to write out a correct prescription for a simple laxative pill containing cascara and belladonna, though they were ready and eager to discuss the most abstruse and recondite clinical syndromes.

It has been the object of this survey to present modern trends in prescribing in an objective and uncontroversial manner. While it is the aim of us all to give our patients the best treatment possible it is also our duty to consider the means at the country's disposal. Good prescribing is often economical prescribing, and it is not improbable that the rewards of thoughtfulness in this respect will be enjoyed by both patient and doctor.

A CASE OF ACUTE BERIBERI COMPLICATING POLYSEROSITIS IN BRITAIN

BY

JAMES THOMSON, M.B., Ch.B., F.R.C.P.Ed.

Lecturer, Department of Medical Diseases of Children,
University of St. Andrews; Paediatric Physician,
Royal Infirmary, Dundee

AND

KENNETH R. KEAY, M.D., M.R.C.P.Ed., D.C.H.

Paediatric Registrar, Royal Infirmary, Dundee

Several cases of beriberi developing in Britain have been reported, and the subject has been reviewed by Jones and Bramwell (1939). Most of the cases have been secondary to chronic alcoholism, as in two cases described by Konstam and Sinclair (1940). Similarly vitamin-B₁ deficiency may be found in the absence of alcoholism if the diet has been subnormal over a long period, as in cases described by Yudkin (1938) and Bates (1941).

Apart from deficient food intake, vitamin-B₁ deficiency may arise from either one or more of the following factors (Harris, 1938): (1) imperfect absorption, as in chronic dysentery; (2) imperfect utilization, as in hepatic cirrhosis; (3) increased demand, as in pregnancy.

The case described showed signs similar to those of beriberi secondary to a severe illness, with prompt relief following the intramuscular administration of vitamin B₁.

Case Report

On the night of March 2, 1950, a 12-year-old girl, an only child, complained of headache and pain in the mid-sternal region. She did not sleep that night, and the next day was off her food and vomited at intervals. On the following day her own doctor diagnosed pneumonia, and a course of

sulphonamide was begun. As there was no improvement she was admitted to hospital on March 7. She did not complain of cough or of sputum, had not previously been breathless, and showed no cyanosis. During the previous two months her mother had noticed that she had not wanted to play and that she had been inclined to sweat at night. There had been no loss of appetite, but there was some constipation. She did not complain of sore tongue, and oedema had not been noticed.

She had had whooping-cough complicated by pneumonia at the age of 3, diphtheria thereafter, and then measles with pulmonary congestion at the age of 7. Her mother and father were both alive and well and there was no history or sign of tuberculosis in the family. Her diet prior to admission was quite normal in quality and amount, including meat, liver, bacon and eggs, much milk, vegetables in moderation, and a great deal of fruit. Her mother re-

On March 10 Mantoux 1:1,000 was positive and E.S.R. was 29 mm. in the first hour (micro-method; normal 10 mm.). Pericardial tap was carried out and 20 ml. straw-coloured fluid withdrawn, containing a large number of polymorphonuclear cells and 5.75 g. of protein %. No micro-organisms could be demonstrated in the fluid and microscopical examination for acid-fast bacilli was negative. On March 14 the liver was enlarged to $2\frac{1}{2}$ in. (6.3 cm.) below the costal margin and was tender on pressure. Neck veins were engorged but no ascites was present. On the 17th she began to show some clinical improvement, with decrease in liver size and in the volume of the effusion.

An x-ray film of the chest on March 27 showed that the pericardial effusion continued to diminish, but there was a pleural effusion on the right side extending up to the eighth rib. Next day she complained of pains in her elbows, which were red and slightly tender. On the 29th she complained of pain in the left side of the neck, and the left side of the face became oedematous. There was no sign of glandular enlargement of the neck.

On March 30 the left side of the chest was oedematous anteriorly, and dullness to percussion became marked on the right side. The temperature was 100.8° F. (38.2° C.); the pulse rate had risen to 156 and respiration rate to 54. Puncture of the right pleural cavity yielded 9 oz. (255 ml.) of blood-stained fluid which contained 2.5 g. of protein per 100 ml., with lymphocytes and a few polymorphs. A large pleural effusion then became evident on the left side of the chest. Streptomycin, 0.5 g. twice daily, was given intramuscularly from March 31 to May 4.

During the next few days the facial oedema became less and the temperature, pulse, and respiratory rate settled, and E.S.R. on April 4 was only 5 mm. in the first hour. Despite this she became more dyspnoeic and cyanosed. On April 3 pericardial tap was attempted, but no fluid was obtained. Aspiration of the left pleural cavity carried out on April 4, produced 30 oz. (850 ml.) of straw-coloured but not blood-stained fluid. This fluid contained red blood cells and mononuclear cells.

From this time, four weeks after admission, she was given a salt-free diet and her fluid intake was restricted to 30 oz. (850 ml.) a day on account of increasing breathlessness and cyanosis. "Digoxin" was begun by mouth and pushed to the limits of tolerance; this was continued in a dosage of 0.25 mg. twice a day until April 11; when it was reduced to 0.25 mg. once daily until May 8. During this period she was extremely ill, requiring continuous oxygen to relieve cyanosis and paraldehyde four-hourly for her restlessness. There was oedema of the legs and sacral region as well as of her left arm and left side of face.

Mersalyl, 1 ml., given intramuscularly on April 9 and 11, on each occasion produced a copious diuresis for one day, as shown in the Chart. By April 10 the respiratory rate, temperature, and pulse rate were more settled, but were 35 , 98.2° F. (36.8° C.), and 110 respectively. On April 14 the legs were still very oedematous and the skin of the legs and upper arms was noted to be scaly. Mersalyl, 1 ml., was repeated on the 17th with similar result, but she remained oedematous and the liver was enlarged below the umbilicus. An x-ray film of the chest on the 17th showed the persistence of a bilateral pleural effusion, which obscured the heart outline.

The fluid-balance chart illustrates the low output in comparison with the intake between the times on which mersalyl was given, despite digoxin and a salt-free diet. Up to this

Chart showing fluid balance

marked that the girl appeared to have grown very tall during the previous year and "was going dark under the eyes."

On examination on March 7 respirations were rapid and she was pale. The tongue was dry and coated, but there was no evidence of glossitis and the fauces were clear. The pulse rate was 110, regular in time and force; temperature 99.8° F. (37.7° C.), respirations 24. The apex beat was palpable just inside the nipple line, in the fourth left interspace 3 in. (7.5 cm.) from the mid-sternal line. There were no murmurs. The chest moved evenly with respirations and the trachea was central. The percussion note was impaired over the right lung anteriorly and there were inspiratory crepitations in the right mid-zone anteriorly. Breath sounds were bronchovesicular. Vocal resonance and fremitus were normal. Thorough examination of the abdomen and central nervous system revealed no abnormality. Blood white cell count was 24,600 per c.mm.

Treatment was begun with penicillin and sulphadimidine. This produced no improvement, and an x-ray film of the chest one day after admission showed the presence of a large pericardial effusion and normal lung fields. At that time she had orthopnoea and a short irritating cough. Re-examination of the heart clinically showed extension of deep cardiac dullness up to the third left rib and muffling of the heart sounds at all areas except the apex.

time the urine had contained albumin to the amount of 0.5 g. per litre per 24 hours, but there was no microscopical abnormality. On April 24 plasma albumin was 3.4 g.% and globulin 2.85 g.%.

Because of the unusual distribution of the oedema, its lack of response to treatment, and the presence of tenderness of the calves, 25 mg. of vitamin B₁ was given intramuscularly on alternate days, beginning on April 26. There was a rapid and dramatic improvement in the girl's condition. The diuresis, which had begun with an intramuscular injection of 1 ml. of mersalyl on April 26, continued for 13 days. Within 48 hours the oedema of the left arm had disappeared and that of the left leg was much less. On April 29 venous congestion in the neck was much less marked. By May 10 there was no oedema of the face, arms, legs, or sacral region. The calves were no longer tender and the liver was now only one fingerbreadth below the costal margin.

More remarkable than the diuresis, however, was the change in the patient's facies. Within 24 hours of beginning vitamin-B₁ therapy her appearance changed from one of distress to one of convalescence, and she obviously felt much better and much happier. Her appetite improved rapidly and her dyspnoea at rest disappeared. Vitamin-B₁ therapy was stopped on May 19, by which time the fluid intake and output approximated to one another, while an x-ray film of the chest showed a normal cardiac outline and the left pleural effusion clearing well, but with only slight improvement on the right side.

She was allowed up for a short while on June 28. A few days later she noticed that her hair was falling out in considerable quantity. The dermatologist (Dr. G. W. Senter) described the alopecia as of the diffuse type commonly associated with serious illness. This loss of hair did not become excessive and she continued to improve. Her serious condition had prevented her being weighed until June 7, when she was 5 st. 7 lb. (34.9 kg.). Thereafter her weight rose slowly to 5 st. 13½ lb. (37.9 kg.) on July 26.

On September 1 there was no evidence of oedema or signs of vitamin deficiency in the eyes, tongue, lips, or skin. Apart from the persistence of her right pleural effusion, the only findings of note were a network of prominent veins over the upper anterior part of the chest in the absence of congestion of the external jugular veins, and purple striae similar to striae gravidarum over the buttocks, lower thigh, and dorsum of the feet, most marked on the left side.

X-ray films of the chest on June 6 and August 29 had shown a slight increase in the right pleural effusion. Because of this, vitamin B₁, 25 mg., was resumed on September 1, being given intramuscularly on alternate days. On September 7, 30 oz. (850 ml.) of blood-stained fluid was withdrawn from the right pleural cavity. To ensure a more balanced intake of the vitamin-B complex, and in view of the increase of the pleural effusion, treatment was begun on September 15 with one tablet three times a day of "benerva" compound, which contains 1 mg. of aneurin, 1 mg. of riboflavin, and 15 mg. of nicotinic acid amide. There ensued an immediate increase in the fluid output, similar to that obtained from vitamin B₁ alone earlier in the illness. This moderate diuresis continued for the next three to four weeks, but with little change in the amount of fluid in the right pleural cavity. On October 10 the Hb was 95%, the white cell count 8,600, and E.S.R. 12 mm. in the first hour. On discharge to a pleurisy unit on October 27 her general condition was excellent despite the persistence of the right pleural effusion. She was eating well and gaining weight, and had no trace of oedema or respiratory distress. The purple striae on the limbs and prominent superficial veins over the chest still persisted, however.

Discussion

This girl's illness may be subdivided into four phases: (1) the prodromal period, culminating in a severe illness with pericarditis and bilateral pleurisy with effusion; (2)

temporary improvement during the third and fourth weeks in hospital, when temperature, pulse, and respiratory rate were settling and the E.S.R. was reduced to 5 mm. in the first hour; (3) recurrence of dyspnoea, with appearance of oedema and considerable hepatic enlargement, death appearing imminent from congestive heart failure; and (4) rapid regression of oedema and dyspnoea at the start of vitamin-B₁ therapy and continued improvement thereafter. Although no organism was isolated from the effusions and several guinea-pig inoculations were negative, it is probable that the polyserositis was due to tuberculosis.

The presence of vitamin-B₁ deficiency at the onset of the illness is considered unlikely in view of the absence of any predisposing factors, such as alcoholism, poor diet, chronic dysentery, malabsorption, or hepatic disease. In addition the acute and febrile onset of the illness and the finding of haemorrhagic serous effusions make it unlikely that vitamin-B₁ deficiency was the cause of the initial disease. According to Bicknell and Prescott (1942) the serous effusions in beriberi are of a clear greenish-yellow colour. The dramatic and immediate response to vitamin B₁ intramuscularly suggests, however, that the severe dyspnoea, oedema, and hepatic enlargement which developed after the acute illness were due to deficiency of vitamin B₁. It will be appreciated that vitamin B₁ possesses diuretic properties, apart from its action as a vitamin (Bicknell and Prescott, 1942). The improvement in the patient's general condition in this case, however, was as dramatic as was the diuresis. Jones and Bramwell (1939) state that vitamin B₁ has no effect on the normal heart or on cardiac failure due to other causes. In this case the lack of response to routine treatment makes it unlikely that the severe cardiac failure was due to a simple toxic myocarditis, and indeed Sweeney (1940) states that myocarditis is quite rare in pulmonary tuberculosis and makes no mention of beriberi as a complicating factor. One case of beriberi developing in a man aged 56 with pulmonary tuberculosis was described by Farber and Miller (1945).

Sumner (1949) describes three cases of pulmonary tuberculosis developing signs of vitamin-B deficiency while on streptomycin therapy, but these were signs mainly of riboflavin and nicotinic acid deficiency, and the patients had been on streptomycin over much longer periods. Weiss and Wilkins (1937) found cardiovascular disturbances due to vitamin-B₁ deficiency in 35 of 5,506 admissions to hospital and consider it commoner than congenital heart disease, adhesive pericarditis, or thyroid heart disease. As in a case of beriberi described by Konstam and Sinclair (1940), there was no enlargement of the heart in our patient with the onset of oedema, and consequently no alteration in the size of the heart following vitamin-B₁ therapy. There was little reduction in the pulse rate from the beginning to the end of the vitamin-B₁ injections.

The vitamin-B₁ deficiency in this patient may have arisen from the increased metabolism associated with a severe infection. Himwich *et al.* (1931) and Hendricks (1933) have shown that vitamin-B complex requirements are proportional to the body metabolism. Contributory factors might be the poor diet taken in the first few weeks of the illness, as the body is unable to store vitamin B₁ for any considerable length of time (Harris, 1938).

We have been unable to trace in the British literature any cases of vitamin-B₁ deficiency secondary to severe infection. This is surprising, as the pyrexial illness in this case did not exceed a period of five weeks. One possible explanation of this, apart from any hypothetical constitutional factor, is that at the time of her illness this girl was pubescent. Ashworth and Sutton (1942) have shown the adverse effect of oestrogen on the utilization of the vitamin-B complex. On admission this girl had a good growth of pubic hair and marked early development of the mammae. It may be that the presumably high level of oestrogen in her circulation at that time impaired her utilization of vitamin B₁ and so contributed to the production of clinical signs.

In addition to the deficiency of vitamin B₁ the temporary presence of hyperkeratosis and of some darkening of the skin suggest some deficiency of vitamin A and of nicotinic acid. Both signs regressed completely after cure of the vitamin-B₁ deficiency and the taking of a normal diet. There were never any signs of riboflavin deficiency.

ADDENDUM.—During 1951 it became obvious that constrictive pericarditis had developed. In consultation with Professor I. G. W. Hill and Mr. M. Fallon it was decided to carry out pericardectomy, which was done on June 5, 1951. The patient made an uneventful recovery, and is now (January, 1952) attending school once more. Vitamin supplements were continued until the time of operation. Tuberculous tissue was found in the parietal pericardium removed at operation.

Summary

A case of multiple vitamin deficiency presenting the clinical picture of acute beriberi is reported in a patient suffering from polyserositis, possibly of tuberculous origin.

It is suggested that the toxic process causing the polyserositis also produced the beriberi symptoms.

No similar case has been discovered in the British literature.

We wish to thank Professor W. J. Tulloch and his staff for bacteriological investigations, Professor A. C. Lendrum, Dr. R. P. Cook, and Dr. J. H. Prain for biochemical assistance, Dr. G. W. Senter for dermatological advice, and Sister M. I. Ansell for her help and nursing care.

GRANULOMATOUS ULCER OF THE NOSE TREATED WITH CHLORAMPHENICOL

BY

I. B. SNEDDON, M.B., Ch.B., M.R.C.P.

Consultant Dermatologist, Rupert Hallam Department of
Dermatology, Royal Infirmary, Sheffield

AND

J. COLQUHOUN, M.B., Ch.B.

Consultant Bacteriologist, Royal Infirmary, Sheffield

Some 35 cases of progressive granulomatous ulcers of the nose, face, and palate of unknown aetiology have been reported since 1896, when McBride first described a case of rapid ulcerative destruction of the nose and face. The literature on the subject has been reviewed by Stewart (1933a), Hoover (1941), Hargrove *et al.* (1946), and Williams (1949). No curative treatment has as yet been discovered; the course of the disease is slowly progressive, ending fatally in most cases. There have been only four reports of recovery. Woods's (1921) second case was healed after implantation of radium needles, and McArthur (1925) used x-ray therapy successfully. Schütz (1938) is quoted by Hoover as having reported a spontaneous cure, and Hoover himself

described an atypical case which recovered. Since the advent of antibiotics there have been reports by Hargrove *et al.* (1946) and Williams (1949). In the case described by Hargrove *et al.* penicillin appeared to control the spread of the lesion, but the patient died from pneumonia. In Williams's first case the patient died from exhaustion despite intensive treatment with penicillin, and penicillin-resistant staphylococci were cultured on numerous occasions from the ulcerated area on the nose, and from other lesions which developed on the arms and legs. The other two cases described by Williams (1949) were also fatal, but the cause of death was stated to be a lymphoma in one case and periarteritis nodosa in the other. The following case of this rare condition is considered worthy of record, as a penicillin-resistant staphylococcus was isolated repeatedly from the ulcerated area and treatment with chloramphenicol controlled the infection and resulted in healing of the ulcer, "aureomycin" previously having failed to do so.

Case Report

A married woman aged 35, employed as a part-time assistant nurse at the Sheffield Royal Infirmary, underwent an operation for submucous resection of the nasal septum on June 26, 1950. The operation was successful in relieving her nasal obstruction and she appeared to recover satisfactorily. On August 10, however, she developed a painful pustule in the left nostril, and was treated with penicillin cream locally and procaine penicillin systemically—600,000 units daily for 10 days. By this time an ulcer extending from the floor of the left nostril to the upper lip was present. She was referred to the skin department on September 4. She was not taking drugs.

Examination revealed an ulcer spreading from the floor of the left nostril to the ala nasi and to the upper lip. The ulcer was covered with a leathery black crust, and the spreading edge was raised and showed firm induration extending 1 cm. beyond the visible margin. At the edge of the crust there were small vesicles. The left cheek and lower eyelid were swollen and oedematous. The regional lymph nodes were not enlarged. Though the ulcer was painful she did not complain of constitutional symptoms and was not febrile. The ulcer was presumed pyogenic in origin, but investigations were carried out to exclude diphtheria, syphilis, anthrax, actinomycosis, and the possibility of an underlying foreign body. No foreign body was found in the nose. Blood Wassermann and Kahn reactions were negative. Radiography of the sinuses and bones of the face and teeth showed no abnormality. A blood count gave 5,000 white cells per c.mm. (52% polymorphs, 38% lymphocytes, 5% monocytes, 5% eosinophils).

Culture of aerobic and anaerobic swabs from the nose and ulcer yielded a mixed growth of a haemolytic streptococcus and *Staphylococcus pyogenes*, and a corynebacterium which was later proved non-virulent to guinea-pigs. No anaerobic streptococcus was isolated. The staphylococcus was found to be sensitive to 1,000 units of penicillin per ml., 500 µg. of streptomycin per ml., 6 µg. of chloramphenicol per ml., and 0.375 µg. of aureomycin per ml. In view of the continued spread of the ulceration the patient was admitted to the ward on September 9 and given aureomycin 250 mg. three-hourly, and applications of saline to the ulcer. On September 14 the ulcer had ceased to extend but showed no sign of healing. Repeated cultures from inside the nose and from the ulcer revealed a *Staph. pyogenes* with the same sensitivity to the antibiotics as above. It was at this stage that a diagnosis of so-called malignant granuloma of the nose was first considered. In view of the grave prognosis if this diagnosis was correct and the success of radiotherapy in the past, superficial x-ray therapy, 200 r, was given to the upper lip and the patient was transfused with 2 pints (1.14 litres) of fresh blood.
